Preface

The complete XENIX Reference Manual is actually divided into six parts and distributed as individual reference sections in the various volumes of the XENIX Operating, Text Processing, and Development Systems. The following table lists the name, content, and location of each reference section.

Section	Description	XENIX Volume
C	Commands – used with the XENIX Operating System.	User's Reference
CP	Programming Commands – used with the Development System.	Programmer's Reference
CT	Text Processing Commands – used with the Text Processing System.	Text Processing Guide
DOS	Routines – used with the Development System	Programmer's Reference
F	File Formats – description of various system files not defined in section M.	User's Reference
HW	Hardware specific manual pages – information about XENIX procedures specific to your computer.	Run Time Environment
M	Miscellaneous – information used for access to devices, system maintenance, and communications.	User's Reference
S	System Calls and Library Routines – available for C and assembly language programming.	Programmer's Reference

In the manual pages, a given command, routine, or file is referred to by name and section. For example, the programming command “cc”, which is described in the Programming Commands (CP) section, is listed as cc(CP).

The alphabetized table of contents given on the following pages is a complete listing of all XENIX commands, system calls, library routines, and file formats. The permuted index, found at the end of the *XENIX User's Reference*, and the the end of the *XENIX Programmer's Reference*, is useful in matching a desired task with the manual page that dexcribes it.

Alphabetized List

Commands, Systems Calls, Library Routines and File Formats

a.out	<i>a.out</i> (F)	bdos	<i>bdos</i> (DOS)
a64l	<i>a64l</i> (S)	bessel	<i>bessel</i> (S)
abort	<i>abort</i> (S)	bfs	<i>bfs</i> (C)
abs	<i>abs</i> (S)	boot	<i>boot</i> (HW)
accept	<i>accept</i> (C)	brk	<i>sbrk</i> (S)
access	<i>access</i> (S)	brkctl	<i>brkctl</i> (S)
acct	<i>acct</i> (F)	bsearch	<i>bsearch</i> (S)
acct	<i>acct</i> (S)	cabs	<i>hypot</i> (S)
acctcom	<i>acctcom</i> (C)	cal	<i>cal</i> (C)
accton	<i>accton</i> (C)	calendar	<i>calendar</i> (C)
acos	<i>trig</i> (S)	calloc	<i>malloc</i> (S)
adb	<i>adb</i> (CP)	cancel	<i>lp</i> (C)
admin	<i>admin</i> (CP)	cat	<i>cat</i> (C)
alarm	<i>alarm</i> (S)	cb	<i>cb</i> (CP)
aliases	<i>aliases</i> (M)	cc	<i>cc</i> (CP)
aliases.hash	<i>aliases</i> (M)	cd	<i>cd</i> (C)
aliashash	<i>aliashash</i> (M)	cdc	<i>cdc</i> (CP)
ar	<i>ar</i> (CP)	ceil	<i>floor</i> (S)
ar	<i>ar</i> (F)	cflow	<i>cflow</i> (CP)
ascii	<i>ascii</i> (M)	cgets	<i>cgets</i> (DOS)
asctime	<i>ctime</i> (S)	chdir	<i>chdir</i> (S)
asin	<i>trig</i> (S)	checkcw	<i>cw</i> (CT)
asktime	<i>asktime</i> (C)	checkeq	<i>eqn</i> (CT)
assert	<i>assert</i> (S)	checklist	<i>checklist</i> (F)
assign	<i>assign</i> (C)	checkmm	<i>checkmm</i> (CT)
asx	<i>asx</i> (CP)	chgrp	<i>chgrp</i> (C)
at	<i>at</i> (C)	chmod	<i>chmod</i> (C)
atan	<i>trig</i> (S)	chmod	<i>chmod</i> (S)
atan2	<i>trig</i> (S)	chown	<i>chown</i> (C)
atof	<i>atof</i> (S)	chown	<i>chown</i> (S)
atof	<i>strtod</i> (S)	chroot	<i>chroot</i> (C)
atoi	<i>atof</i> (S)	chroot	<i>chroot</i> (S)
atoi	<i>strtol</i> (S)	chsize	<i>chsize</i> (S)
atol	<i>atof</i> (S)	clearerr	<i>ferror</i> (S)
atol	<i>strtol</i> (S)	clock	<i>clock</i> (M)
autoboot	<i>autoboot</i> (M)	clock	<i>clock</i> (S)
awk	<i>awk</i> (C)	clockrate	<i>clockrate</i> (C)
backup	<i>backup</i> (C)	close	<i>close</i> (S)
backup	<i>backup</i> (F)	closedir	<i>directory</i> (S)
badtrk	<i>badtrk</i> (M)	clri	<i>clri</i> (C)
banner	<i>banner</i> (C)	cmchk	<i>cmchk</i> (C)
basename	<i>basename</i> (C)	cmos	<i>cmos</i> (HW)
batch	<i>at</i> (C)	cmp	<i>cmp</i> (C)
bc	<i>bc</i> (C)	col	<i>col</i> (CT)
bdiff	<i>bdiff</i> (C)	comb	<i>comb</i> (CP)

comm	<i>comm</i> (C)	diction	<i>diction</i> (CT)
config	<i>config</i> (CP)	diff	<i>diff</i> (C)
console	<i>console</i> (HW)	diff3	<i>diff3</i> (C)
conv	<i>conv</i> (S)	diffmk	<i>diffmk</i> (CT)
copy	<i>copy</i> (C)	dir	<i>dir</i> (F)
core	<i>core</i> (F)	dircmp	<i>dircmp</i> (C)
cos	<i>trig</i> (S)	directory	<i>directory</i> (S)
cosh	<i>sinh</i> (S)	dirname	<i>dirname</i> (C)
cp	<i>cp</i> (C)	disable	<i>disable</i> (C)
cpio	<i>cpio</i> (C)	diskcmp	<i>diskcmp</i> (C)
cpio	<i>cpio</i> (F)	diskcp	<i>diskcp</i> (C)
c++	<i>c++</i> (CP)	divvy	<i>divvy</i> (C)
cprintf	<i>cprintf</i> (DOS)	dmesg	<i>dmesg</i> (C)
cputs	<i>cputs</i> (DOS)	dos	<i>dos</i> (C)
creat	<i>creat</i> (S)	doscat	<i>doscat</i> (C)
creatsem	<i>creatsem</i> (S)	doscat	<i>doscat</i> (C)
cref	<i>cref</i> (CP)	doscp	<i>doscp</i> (C)
cron	<i>cron</i> (C)	doscp	<i>doscp</i> (C)
cscanf	<i>cscanf</i> (DOS)	dosdir	<i>dosdir</i> (C)
csh	<i>csh</i> (C)	dosdir	<i>dosdir</i> (C)
csplit	<i>csplit</i> (C)	dosexterr	<i>dosexterr</i> (DOS)
ctags	<i>ctags</i> (CP)	dosld	<i>dosld</i> (CP)
ctermid	<i>ctermid</i> (S)	dosls	<i>dosls</i> (C)
ctime	<i>ctime</i> (S)	dosls	<i>dosls</i> (C)
ctype	<i>ctype</i> (S)	dosmkdir	<i>dosmkdir</i> (C)
cu	<i>cu</i> (C)	dosrm	<i>dosrm</i> (C)
curses	<i>curses</i> (S)	dosrm	<i>dosrm</i> (C)
cuserid	<i>cuserid</i> (S)	dosrmdir	<i>dosrmdir</i> (C)
custom	<i>custom</i> (C)	dosrmdir	<i>dosrmdir</i> (C)
cut	<i>cut</i> (CT)	drand48	<i>drand48</i> (S)
cw	<i>cw</i> (CT)	dtype	<i>dtype</i> (C)
cwcheck	<i>cw</i> (CT)	du	<i>du</i> (C)
cxref	<i>cxref</i> (CP)	dump	<i>dump</i> (C)
daemon.mn ..	<i>daemon.mn</i> (M)	dump	<i>dump</i> (F)
date	<i>date</i> (C)	dumpdir	<i>dumpdir</i> (C)
dbm	<i>dbm</i> (S)	dup	<i>dup</i> (S)
dc	<i>dc</i> (C)	dup2	<i>dup2</i> (S)
dd	<i>dd</i> (C)	8087	<i>8087</i> (HW)
deassign	<i>assign</i> (C)	8087	<i>8087</i> (M)
default	<i>default</i> (M)	86rel	<i>86rel</i> (F)
defopen	<i>defopen</i> (S)	echo	<i>echo</i> (C)
defread	<i>defopen</i> (S)	ecvt	<i>ecvt</i> (S)
delete	<i>dbm</i> (S)	ed	<i>ed</i> (C)
delta	<i>delta</i> (CP)	edata	<i>end</i> (S)
deroff	<i>deroff</i> (CT)	egrep	<i>grep</i> (C)
devnm	<i>devnm</i> (C)	enable	<i>enable</i> (C)
df	<i>df</i> (C)	end	<i>end</i> (S)
dial	<i>dial</i> (M)	endgrent	<i>getgrent</i> (S)
dial	<i>dial</i> (S)	endpwent	<i>getpwent</i> (S)

enduntent	getut(S)	filelength	filelength(DOS)
env	env(C)	fileno	ferror(S)
environ	environ(M)	find	find(C)
eof	eof(DOS)	finger	finger(C)
eqn	eqn(CT)	firstkey	dbm(S)
eqnchar	eqnchar(CT)	fixhdr	fixhdr(C)
eqncheck	eqn(CT)	fixperm	fixperm(M)
erand48	drand48(S)	floor	floor(S)
erf	erf(S)	flushall	flushall(DOS)
erfc	erf(S)	fmod	floor(S)
errno	perror(S)	fopen	fopen(S)
etext	end(S)	fork	fork(S)
ex	ex(C)	format	format(C)
exec	exec(S)	fp-off	fp-off(DOS)
execl	exec(S)	fp-seg	fp-seg(DOS)
execle	exec(S)	fprintf	printf(S)
execvp	exec(S)	fputc	fputc(DOS)
execv	exec(S)	fputc	putc(S)
execve	exec(S)	fputchar	fputchar(DOS)
execvp	exec(S)	fputs	puts(S)
_exit	exit(S)	fread	fread(S)
exit	exit(DOS)	free	malloc(S)

Contents

Commands (C)

intro	Introduces XENIX commands.
accept, reject	Allows/prevents print requests
acctcom	Searches for and prints process accounting files.
accton	Turns on accounting.
asktime	Prompts for the correct time of day.
assign, deassign	Assigns and deassigns devices.
at, batch	Executes commands at a later time.
awk	Searches for and processes a pattern in a file.
backup	Performs incremental file system backup.
banner	Prints large letters.
basename	Removes directory names from pathnames.
bc	Invokes a calculator.
bdiff	Compares files too large for <i>diff</i> .
bfs	Scans big files.
cal	Prints a calendar.
calendar	Invokes a reminder service.
cat	Concatenates and displays files.
cd	Changes working directory.
chgrp	Changes group ID.
chmod	Changes the access permissions of a file or directory.
chown	Changes owner ID.
chroot	Changes root directory for command.
clockrate	Sets interrupt timer clock frequency.
cli	Clears inode.
cmchk	Reports hard disk block size.
cmp	Compares two files.
comm	Selects or rejects lines common to two sorted files.
copy	Copies groups of files.
cp	Copies files.
cpio	Copies file archives in and out.
cron	Executes commands at specified times.
csh	Invokes a shell command interpreter with C-like syntax.
csplit	Splits files according to context.
cu	Calls another XENIX system.
custom	Allows user to customize XENIX.
date	Prints and sets the date.

dc	Invokes an arbitrary precision calculator.
dd	Converts and copies a file.
devnm	Identifies device name.
df	Reports the number of free disk blocks.
diff	Compares two text files.
diff3	Compares three files.
dircmp	Compares directories.
dirname	Delivers directory part of pathname.
disable	Turns off terminals.
diskcp	Copies or compares floppy disks.
divvy	Divides disk partitions.
dmesg	System messages displayed on console.
dos, doscat,	
doscp, dosdir,	
dosls, dosmkdir,	
dosrm, dosrmdir	Accesses MS-DOS files.
dtype	Determines disk type.
du	Summarizes disk usage.
dump	Incremental file system backup.
dumpdir	Prints the names of files on a backup archive.
echo	Echoes arguments.
ed	Invokes the text editor.
enable	Turns on terminals.
env	Sets environment for command execution.
ex	Invokes a text editor.
expr	Evaluates arguments as an expression.
factor	Factor a number.
false	Returns with a nonzero exit value.
fdisk	Maintains disk partitions.
file	Determines file type.
find	Finds files.
finger	Finds information about users.
fixhdr	Changes binary file header
format	Formats floppy disks.
fsck	Checks and repairs file systems.
getopt	Parses command options.
grep, egrep, fgrep	Searches a file for a pattern.
grpcheck	Checks group file.
haltsys	Closes out the file systems and halts the CPU.
hd	Displays files in hexadecimal format.
head	Prints the first few lines of a stream.
id	Prints user and group IDs and names.
imprint	Print on an IMAGEN printer.
ipcrm	Removes messages.
ipcs	Process communication report.
ips	IMAGEN serial sequence packet protocol handler.

join	Joins two relations.
kill	Terminates a process.
l	Lists directory contents.
lc	Lists directory contents in columns.
line	Reads one line.
ln	Makes a link to a file.
logname	Gets login name.
lp, lpr, cancel	Sends files to the lineprinter queue for printing.
lpadmin	Line printer, configure.
lpinit	Line printer, add.
lpsched, lpshut,	
lpmove	Start/stop line printer request scheduler.
lpstat	Line printer status.
ls	Gives information about contents of directories.
mail	Sends, reads or disposes of mail.
mesg	Permits or denies messages sent to a terminal.
mkdev	Calls script to create devices.
mkdir	Makes a directory.
mkfs	Constructs a file system.
mknod	Builds special files.
mkuser	Adds a login ID to the system.
more	Views a file one screen full at a time.
mount	Mounts a file structure.
mv	Moves or renames files and directories.
ncheck	Generates names from inode numbers.
netutil	Administers the XENIX network.
newform	Changes format of a text file.
newgrp	Logs user in to a new group.
news	Prints news items.
nice	Runs a command at a different priority.
nl	Adds line numbers to a file.
nohup	Runs a command immune to hangups and quits.
od	Displays files in octal format.
pack, pcat,	
unpack	Compresses and expands files.
passwd	Changes login password.
pg	File perusal filter for soft copy terminals.
pr	Prints files on the standard output.
ps	Reports process status.
pstat	Reports system information.
pwadmin	Performs password aging administration.
pwcheck	Checks password file.
pwd	Prints working directory name.

quot	Summarizes file system ownership.
random	Generates a random number.
rcp	Copies files across XENIX systems.
red	Invokes a restricted version of <i>ed</i> (C).
remote	Executes commands on a remote XENIX system.
restore	Invokes incremental file system restorer.
rm, rmdir	Removes files or directories.
rmdir	Removes directories.
rmuser	Removes a user from the system.
rsh	Invokes a restricted shell (command interpreter).
runbig	Run commands too large for memory.
sddate	Prints and sets backup dates.
sdiff	Compares files side-by-side.
sed	Invokes the stream editor.
setcolor	Set screen color.
setmnt	Establishes /etc/mnttab table.
settime	Changes the access and modification dates of files.
sh	Invokes the shell command interpreter.
shutdown	Terminates all processing.
sleep	Suspends execution for an interval.
sort	Sorts and merges files.
split	Splits a file into pieces.
stty	Sets the options for a terminal.
su	Makes the user super-user or another user.
sum	Calculates checksum and counts blocks in a file.
sync	Updates the super-block.
sysadmin	Performs file system backups and restores files.
tail	Delivers the last part of a file.
tar	Archives files.
tee	Creates a tee in a pipe.
test	Tests conditions.
touch	Updates access and modification times of a file.
tr	Translates characters.
true	Returns with a zero exit value.
tset	Sets terminal modes.
tty	Gets the terminal's name.
umask	Sets file-creation mode mask.
umount	Dismounts a file structure.
uname	Prints the current XENIX name.
uniq	Reports repeated lines in a file.
units	Converts units.
uuclean	Clean-up the uucp spool directory.

uucp, uulog,	Copies files from XENIX to XENIX.
uuname	uucp, administers control files.
uuinstall	Uucp status inquiry and job control.
uustat	Monitor uucp network.
uusub	Public XENIX-to-XENIX file copy.
uuto, uupick	Executes command on remote XENIX.
uux	Invokes a screen-oriented display editor.
vi	Invokes the visual shell.
vsh	Awaits completion of background processes.
wait	Writes to all users.
wall	Counts lines, words and characters.
wc	Identifies files.
what	Lists who is on the system.
who	Determines who is doing what.
whodo	Writes to another user.
write	Constructs and executes commands.
xargs	Prints string repeatedly.
yes	

Name

intro - Introduces XENIX commands.

Description

This section describes use of the individual commands available in the XENIX Operating System. Each individual command is labeled with either a C, a CP, or a CT for easy reference from other volumes. The letter "C" stands for "command". The letters "P" and "T" stand for commands that come with the optional XENIX Development System (Programming) and the XENIX Text Processing System, respectively. For example, the reference *date*(C) indicates a reference to a discussion of the **date** command in the C section; the reference *cc*(CP) indicates a reference to a discussion of the **cc** command in the XENIX Development System; and the reference *spell*(CT) indicates a reference to a discussion of the **spell** command in the XENIX Text Processing System. The Text Processing and Development Systems are optional supplemental packages to the standard Operating System.

The "M" Miscellaneous section contains miscellaneous information including a great deal of system maintenance information. Other reference sections include the "S" System Services section, the "DOS" Routines section and the "F" File Format section.

Syntax

Unless otherwise noted, commands described in this section accept options and other arguments according to the following syntax:

name [*option*(*s*)] [*cmdarg*(*s*)]

where:

name Is the name of an executable file.

option - *noargletter*(*s*) or,
 - *argletter*<>*optarg*
 where <> is optional whitespace.

noargletter Is a single letter representing an option without an argument.

argletter Is a single letter representing an option requiring an argument.

<i>optarg</i>	Is an argument (character string) satisfying preceding <i>argletter</i> .
<i>cmdarg</i>	Is a pathname (or other command argument) <i>not</i> beginning with <i>-</i> . <i>-</i> by itself indicates the standard input.

See Also

getopt(C), getopt(S)

Diagnostics

Upon termination, each command returns 2 bytes of status, one supplied by the system and giving the cause for termination, and (in the case of “normal” termination) one supplied by the program (see *wait*(S) and *exit*(S)). The former byte is 0 for normal termination; the latter is customarily 0 for successful execution and nonzero to indicate troubles such as erroneous parameters, bad or inaccessible data. It is called variously “exit code”, “exit status”, or “return code”, and is described only where special conventions are involved.

Notes

Not all commands adhere to the syntax described here.

Name

accept, reject - Allows/prevents print requests to a lineprinter or class of printers.

Syntax

/usr/lib/accept destinations
/usr/lib/reject [-r[reason]] destinations

Description

accept allows *lp*(C) to accept requests for the named *destinations*. A *destination* can be either a printer or a class of printers. Use *lpstat*(C) to find the status of *destinations*.

reject prevents *lp*(C) from accepting requests for the named *destinations*. A *destination* can be either a printer or a class of printers. Use *lpstat*(C) to find the status of *destinations*. The following option is useful with *reject*:

-r[*reason*] Associates a *reason* with disabling (using *disable*(C)) the printer. The *reason* applies to all printers listed up to the next -r option. If the -r option is not present or the -r option is given without a *reason*, then a default *reason* is used. *Reason* is reported by *lpstat*(C). Please see *disable*(C) for an example of *reason* syntax.

Files

/usr/spool/lp/*

See Also

enable(C), lp(C), lpadmin(C), lpinit(C), lpsched(C), lpstat(C), disable(C).

Name

acctcom – Searches for and prints process accounting files.

Syntax

acctcom [[options]][file] . . .

Description

acctcom reads *file*, the standard input, or */usr/adm/pacct*, in the form described by *acct*(F) and writes selected records to the standard output. Each record represents the execution of one process. The output shows the COMMAND NAME, USER, TTYNAME, START TIME, END TIME, REAL (SEC), CPU (SEC), MEAN SIZE (K), and optionally, F (the *fork/exec* flag: 1 for *fork* without *exec*) and STAT (the system exit status).

The command name is prepended with a # if it was executed with super-user privileges. If a process is not associated with a known terminal, a ? is printed in the TTYNAME field.

If no *files* are specified, and if the standard input is associated with a terminal or */dev/null* (as is the case when using *&* in the shell), */usr/adm/pacct* is read, otherwise the standard input is read.

If any *file* arguments are given, they are read in their respective order. Each file is normally read forward, i.e., in chronological order by process completion time. The file */usr/adm/pacct* is usually the current file to be examined; a busy system may need several files, in which case all but the current file will be found in */usr/adm/pacct?*. The *options* are:

- b** Reads backwards, showing latest commands first.
- f** Prints the *fork/exec* flag and system exit status columns in the output.
- h** Instead of showing mean memory size, it shows the fraction of total available CPU time consumed by the process during its execution. This “hog factor” is computed as:

$$(\text{total CPU time})/(\text{elapsed time}).$$
- i** Prints columns containing the I/O counts in the output.
- k** Instead of memory size, shows total kcore-minutes.

- m** Shows mean core size (the default).
- r** Shows CPU factor (user time/(system-time + user-time).)
- t** Shows separate system and user CPU times.
- v** Excludes column headings from the output.
- l line** Shows only processes belonging to terminal */dev/line*.
- u user** Shows only processes belonging to *user* that may be specified by a user ID, a login name that is then converted to a user ID, a *#* which designates only those processes executed with super-user privileges, or *?* which designates only those processes associated with unknown user IDs.
- g group** Shows only processes belonging to *group*. The *group* may be designated by either the group ID or group name.
- d mm/dd** Any *time* arguments following this flag are assumed to occur on the given month and day, rather than during the last 24 hours. This is needed for looking at old files.
- s time** Shows only those processes that existed on or after *time*, given in the form *hr:min:sec*. The *:sec* or *:min:sec* may be omitted.
- e time** Shows only those processes that existed on or before *time*. Using the same *time* for both **-s** and **-e** shows the processes that existed at *time*.
- n pattern** Shows only commands matching *pattern* that may be a regular expression as in *ed* (C) except that **+** means one or more occurrences.
- H factor** Shows only processes that exceed *factor*, where factor is the "hog factor" as explained in option **-h** above.
- I number** Shows driver processes transferring more characters than the cutoff *number*.
- O time** Shows only those processes with operating system CPU time that exceeds *time*.

-C *time*

Shows only those processes that exceed *time* (the total CPU time).

Multiple options have the effect of a logical AND.

Files

/etc/passwd

/usr/adm/pacct

/etc/group

See Also

accton(C), ps(C), su(C), acct(S), acct(F), utmp(M)

Notes

acctcom only reports on processes that have terminated; use *ps* (C) for active processes.

Name

accton – Turns on accounting.

Syntax

accton [*file*]

Description

accton turns on and off process accounting. If no *file* is given then accounting is turned off. If *file* is given, the kernel appends process accounting records. (See *acct* (S) and *acct* (F)).

Files

/etc/passwd	Used for login name to user ID conversions
/usr/adm/pacct	Current process accounting file
/usr/adm/sulogin	Super-user login history file
/etc/wtmp	Login/logout history file

See Also

acctcom(C), acct(S), acct(F), su(C), utmp(M)

Name

asktime – Prompts for the correct time of day.

Syntax

/etc/asktime

Description

This command prompts for the time of day. You must enter a legal time according to the proper format as defined below:

`[[yy]mmd]hhmm`

Here the first *mm* is the month number; *dd* is the day number in the month; *hh* is the hour number (24-hour system); the second *mm* is the minute number; *yy* is the last 2 digits of the year number and is optional. The current year is the default if no year is mentioned.

Examples

This example sets the new time, date, and year to "11:29 April 20, 1985".

Current system time is Wed Nov 3 14:36:23 PST 1985
Enter time ([yymmdd]hhmm): 8504201129

Diagnostics

If you enter an illegal time, *asktime* prompts with:

Try again:

Notes

asktime is normally performed automatically by the system startup file **/etc/rc** immediately after the system is booted; however, it may be executed at any time. The command is privileged, and can only be executed by the super-user.

Systems which autoboot will invoke *asktime* automatically on reboot. On these systems, if you don't enter a new time or press return within 1 minute of invoking *asktime* , the system will use the time value it has. If RETURN alone is entered, the time is unchanged.

Name

assign, deassign – Assigns and deassigns devices.

Syntax

assign [**-u**] [**-v**] [**-d**] [device] ...

deassign [**-u**] [**-v**] [device] ...

Description

assign attempts to assign *device* to the current user. The *device* argument must be an assignable device that is not currently assigned. An *assign* command without an argument prints a list of assignable devices along with the name of the user to whom they are assigned.

deassign is used to “deassign” devices. Without any arguments, *deassign* will deassign all devices assigned to the user. When arguments are given, an attempt is made to deassign each *device* given as an argument.

With these commands you can exclusively use a device, such as a tape drive or floppy drive. This keeps other users from using the device. They have a similar effect as *chown*(C) and *chmod*(C), although they only act on devices in */dev*. Other aspects are discussed further on.

Available options include:

-d

Performs the action of *deassign*. The **-d** option may be embedded in *device* names to assign some devices and deassign others.

-v

Gives verbose output.

-u

Suppresses assignment or deassignment, but performs error checking.

The *assign* command will not assign any assignable devices if it cannot assign all of them. *deassign* gives no diagnostic if the *device* cannot be deassigned. Devices may be automatically deassigned at logout, but this is not guaranteed. *Device* names may be just the beginning of the device required. For example,

assign fd

should be used to assign all floppy disk devices. Raw versions of *device* will also be assigned, e.g., the raw floppy disk devices */dev/rfd?* would be assigned in the above example.

Note that in many installations the assignable devices such as floppy disks have general read and write access, so the *assign* command may not be necessary. This is particularly true on single-user systems. Devices supposed to be assignable with this command should be owned by the user *asg*. The directory */dev* should be owned by *bin* and have mode 755. The *assign* command (after checking for use by someone else) will then make the device owned by whoever invokes the command, without changing the access permissions. This allows the system administrator to set up individual devices that are freely available, assignable (owned by *asg*), or nonassignable and restricted (not owned by *asg* and with some restricted mode).

Note that the first time *assign* is invoked, it builds the assignable devices table */etc/atab*. This table is used in subsequent invocations to save repeated searches of the */dev* directory. If one of the devices in */dev* is changed to be assignable (i.e., owned by *asg*), then */etc/atab* should be removed (by the super-user) so that a correct list will be built the next time the command is invoked.

Return Values

Exit code 0 returned if successful, 1 if problems, 2 if *device* cannot be assigned.

Name

at, *batch* – Executes commands at a later time.

Syntax

at time [date] [+ increment]

at -r job ...

at -l[job ...]

at -q[letter] time [date] [job ...]

Description

at and *batch* read commands from the standard input to be executed at a later time. *at* allows you to specify a time when the commands should be executed, while *batch* executes jobs when the system load level permits.

Standard output and standard error output are mailed to the user unless they are redirected elsewhere. The shell environment variables, current directory, *umask*, and *ulimit* are retained when the commands are executed. Open file descriptors, traps, and priorities are lost.

A user is permitted to use *at* if his name appears in the file */usr/lib/cron/at.allow*. If that file does not exist, the file */usr/lib/cron/at.deny* is checked to determine if the user should be denied access to *at*. If neither file exists, only root is allowed to submit a job. If only the *at.deny* file exists, global usage is permitted. The allow/deny files consist of one user name per line.

The options are:

time The *time* may be specified as 1, 2, or 4 digits. One- and two-digit numbers are taken to be hours, four digits to be hours and minutes. The time may alternately be specified as two numbers separated by a colon, meaning *hour:minute*. A suffix *am* or *pm* may be appended; otherwise a 24-hour clock time is understood. The suffix *zulu* may be used to indicate GMT. The special names *noon*, *midnight*, *now*, and *next* are also recognized.

date An optional *date* may be specified as either a month name followed by a day number (and possibly year number preceded by an optional comma) or a day of the week (fully spelled or abbreviated to three characters). Two special "days", *today* and *tomorrow*, are recognized. If no *date* is

given, **today** is assumed if the given hour is greater than the current hour and **tomorrow** is assumed if it is less. If the given month is less than the current month (and no year is given), next year is assumed.

increment

The optional *increment* is simply a number suffixed by one of the following: **minutes**, **hours**, **days**, **weeks**, **months**, or **years**. (The singular form is also accepted.) Thus, legitimate commands include:

```
at 0815am Jan 24
at 8:15am Jan 24
at now + 1 day
at 5 pm Friday
```

-r Removes jobs previously scheduled by the *at* or *batch* command. Unless you are the super-user, you can only remove your own jobs.

-l Lists all the jobs currently scheduled for the invoking user.

-ql*letter*

Places the specified job in a queue denoted by *letter*, where *letter* is any letter from "a" to "z" (not uppercase). The queue letter is appended to the job number. The following letters have special significance:

```
a  at queue
b  batch queue
c  cron queue
```

at and *batch* write the job number and schedule time to standard error. *batch* submits a batch job. It is almost equivalent to "at now," but with a difference: **batch** goes into a different queue; **at** now will respond with the error message too late.

Examples

The *at* and *batch* commands read the commands to be executed at a later time from the standard input. *sh*(C) provides different ways of specifying standard input. Within your commands, it may be useful to redirect standard output.

The following sequence can be used at a terminal:

```
batch
nroff filename > outfile
<Ctrl-D> (press "Ctrl" and press "D")
```

This sequence, which demonstrates redirecting standard error to a pipe (`|`), is useful in a shell procedure (the sequence of output redirection specifications is significant):

```
batch <<!  
nroff filename 2>&1 >outfile | mail  
loginid  
!
```

To have a job reschedule itself, invoke *at* from within the shell procedure by including code similar to the following within the shell file:

```
echo "sh shellfile" | at 1900 thursday next week
```

Files

/usr/lib/cron	main cron directory
/usr/lib/cron/at.allow	list of allowed users
/usr/lib/cron/at.deny	list of denied users
/usr/lib/cron/queue	scheduling information
/usr/spool/cron/atjobs	spool area

See Also

cron(C), kill(C), mail(C), nice(C), ps(C), sh(C)

Diagnostics

Complains about syntax errors and times out of range.

Name

awk – Searches for and processes a pattern in a file.

Syntax

awk [-Fc] [-f programfile | 'program'] [parameters] [files]

Description

awk scans each input *file* for lines that match patterns specified in *program* or in *programfile*. When a line of *files* matches a pattern, an associated action may be performed. *awk* is useful for compiling information, performing arithmetic on input data, and for doing iterative or conditional processing.

The options are:

-Fc Sets the field separator variable (FS) to the letter “c”.
The default field separators are tab and space.

-f Causes *awk* to take its program from *programfile*.

The arguments are:

programfile A file containing an *awk* program.

program An *awk* program. Programs given on the command line must be enclosed in single quotation marks to prevent interpretation by the shell.

parameters May be passed to *awk* in the form *x=...*, *y=...*, etc.

files The name(s) of the file or files to be processed. If no filename is given, the standard input is used.

An *awk* program consists of statements in the form:

pattern { action }

Pattern-action statements may appear on the *awk* command line or in an *awk* program file.

If no *pattern* is given, all lines in the input file are matched. If no *action* is given, each matched line is displayed on the standard output.

A pattern may be a literal string or a regular expression, or a combination of a regular expression and a field or variable separated by operators.

awk also provides two patterns, BEGIN and END, that can be used to perform actions before the first line is read and after the last line is read, respectively.

To select a range of lines, use two patterns on a single program line, separated by a comma.

An action is a sequence of statements separated by a semicolon, newline, or right brace. See *Statements* later in this section.

Variables

In addition to variables declared and initialized by the user, *awk* has the following program variables:

NR	Number of records.
NF	Number of fields in a record.
FS	Input field separator.
OFS	Output field separator.
RS	Input record separator.
ORS	Output record separator.
\$0	The current record.
\$1, \$ <i>n</i>	Fields in the current record.
OFM	The output format for numbers. The default is %.6g.

FILENAME

The name of the input file currently being read.

Arrays may be used to store data. Arrays do not need to be dimensioned before use. For example, "*w*[*i*]" denotes the *i*th item of array *w*.

Expressions

A pattern match with a field or variable may be tested with the following operators:

- ~ Matches the regular expression.

!~ Does not match the regular expression.

awk processes relational expressions using the following operators:

<	Less than
<=	Less than or equal to
==	Equal to
!=	Not equal to
>=	Greater than or equal to
>	Greater than

Patterns can be combined using the operators:

&&	And
	Or
!	Not

An empty expression-list stands for the whole line. Expressions take on string or numeric values as appropriate, and are built using the following operators:

+	Addition
-	Subtraction
*	Multiplication
/	Division
%	Modulo

Concatenation is indicated by a blank.

The following C operators are also available in expressions:

++	Increment
--	Decrement
+=	Add and assign
-=	Subtract and assign

- *=** Multiply and assign
- /=** Divide and assign
- %=** Modulo and assign

Statements

```

if ( conditional ) statement [ else statement ]
while ( conditional ) statement
for ( expression ; conditional ; expression ) statement
break
continue
{ [ statement ] ... }
variable = expression
print [ expression-list ] [ >expression ]
printf format [ , expression-list ] [ >expression ]
next    #skip remaining patterns on input line

```

- while** Used the same as in C.
- for** The iterative construction. It can be used the same as in the C language, or as an array iterator.
- break** Similar to its C counterpart.
- continue** Similar to its C counterpart.
- print** Prints its arguments on the standard output, or in a file if redirected.
- printf** Prints *expression-list* in the format specified in *format*. See *printf(S)*.
- next** Stops processing the current record and moves to the next record, if any.

Comments are preceded by a number sign (#).

Functions

awk has the following built-in functions:

- exit(*x*)** Terminates the *awk* program. If *x* is given, this value is *awk*'s return value. If *x* is not given, 0 is returned. If the program has an END section, it is invoked before termination.
- exp(*x*)** Exponentiation of the value of *x*.

<code>index(s, t)</code>	Returns the starting position of the leftmost occurrence of <i>t</i> in <i>s</i> . If <i>t</i> is not a substring of <i>s</i> , then <code>index(s, t)</code> is 0.
<code>int(x)</code>	Returns the largest integer less than or equal to <i>x</i> . If <i>x</i> is negative, its value is the smallest integer greater than or equal to <i>x</i> .
<code>length(x)</code>	A function whose value is the number of characters in the string (<i>x</i>). With no arguments, <i>length</i> is equivalent to <code>\$0</code> .
<code>log(x)</code>	Natural logarithm of <i>x</i> .
<code>split(x, y)</code>	Assigns the fields of string <i>x</i> to successive elements of array <i>y</i> .
<code>sqrt(x)</code>	Square root of <i>x</i> .
<code>substr(string, index, length)</code>	Returns the substring of <i>string</i> that begins at <i>index</i> and is <i>length</i> characters long.

Examples

The following displays lines in *file* longer than 72 characters:

```
awk '{length > 72}' file
```

The following prints the first two fields in opposite order:

```
awk '{ print $2, $1 }' file
```

The following adds up the first columns and prints their sum and average:

```
    { s += $1 }
END  { print "sum is", s, " average is", s/NR }
```

The following prints the fields in *file* in reverse order:

```
awk { for (i = NF; i > 0; --i) print $i } file
```

The following prints all lines between start/stop pairs:

```
awk '/start/, /stop/' file
```

The following *awk* program file will print all lines in the object file whose first field is different from the first field in the previous line:

```
$1 != prev { print; prev = $1 }
```

The following program prints a file, filling in page numbers starting at 5:

```
/Page/ { $2 = n++; }  
      { print }
```

The command line has the form: `awk -f program n=5 input`

See Also

`grep(C)`, `lex(CP)`, `malloc(S)`, `sed(C)`
XENIX Text Processing Guide

Notes

Input whitespace is not preserved on output if fields are involved.

There are no explicit conversions between numbers and strings. To force an expression to be treated as a number, add 0 to it; to force it to be treated as a string, concatenate the null string ("") to it.

This command is explained in detail in the *XENIX Text Processing Guide*.

Name

backup – Performs incremental file system backup.

Syntax

backup [*key* [*arguments*] *filesystem*]

Description

backup copies all files changed after a certain date in the date in the *filesystem*. The *key* specifies the date and other options about the backup, where a *key* consists of characters from the set **0123456789kfusd**. The meanings of these characters are described below:

- f** Places the backup on the next *argument* file instead of the default device.
- u** If the backup completes successfully, writes the date of the beginning of the backup to the file **/etc/ddate**. This file records a separate date for each file system and each backup level.
- 0-9** This number is the “backup level”. Backs up all files modified since the last date stored in the file **/etc/ddate** for the same file system at lesser levels. If no date is determined by the level, the beginning of time is assumed; thus the option **0** causes the entire file system to be backed up.
- s** For backups to magnetic tape, the size of the tape is specified in feet. The number of feet is taken from the next *argument*. When the specified size is reached, *backup* will wait for reels to be changed. The default size is 2,300 feet.
- d** For backups to magnetic tape, the density of the tape, expressed in BPI, is taken from the next *argument*. This is used in calculating the amount of tape used per write. The default is 1600.
- k** This option is used when backing up to a block-structured device, such as a floppy disk. The size (in K-bytes) of the volume being written is taken from the next *argument*. If the **k** argument is specified, any **s** and **d** arguments are ignored. The default is to use **s** and **d**.

If no arguments are given, the *key* is assumed to be **9u** and a default file system is backed up to the default device.

The first backup should be a full level-0 backup:

```
backup 0u
```

Next, periodic level 9 backups should be made on an exponential progression of tapes or floppies:

```
backup 9u
```

This progression is shown as follows:

```
1 2 1 3 1 2 1 4 ...
```

where backup 1 is used every other time, backup 2 every fourth, backup 3 every eighth, etc.) When the level-9 incremental backup becomes unmanageable because a tape is full or too many floppies are required, a level-1 backup should be made:

```
backup 1u
```

After this, the exponential series should progress as if uninterrupted. These level-9 backups are based on the level-1 backup, which is based on the level-0 full backup. This progression of levels of backups can be carried as far as desired.

The default file system and the backup device depend on the settings of the variables DISK and TAPE, respectively, in the file */etc/default/backup*.

Files

<i>/etc/ddate</i>	Records backup dates of file system/level
<i>etc/default/backup</i>	Default backup information

See Also

XENIX Operations Guide
cpio(C), *default(M)*, *dumpdir(C)*, *restore(C)*, *sddate(C)*, *backup(F)*

Diagnostics

If the backup requires more than one volume (where a volume is likely to be a floppy disk or tape), you will be asked to change volumes. Press RETURN after changing volumes.

Notes

Sizes are based on 1600 BPI for blocked tape; the raw magnetic tape device has to be used to approach these densities. Write errors to the backup device are usually fatal. Read errors on the file system are ignored.

It is not possible to successfully *restore* an entire active root file system.

Warning

When backing up to floppy disks, be sure to have enough *formatted* floppies ready before starting a backup.

Name

banner – Prints large letters.

Syntax

banner strings

Description

banner prints its arguments (each up to 10 characters long) in large letters on the standard output. This is useful for printing names at the front of printouts.

See Also

echo(C)

Name

basename – Removes directory names from pathnames.

Syntax

basename string [suffix]

Description

basename deletes any prefix ending in / and the *suffix* (if present in *string*) from *string*, and prints the result on the standard output. The result is the “base” name of the file, i.e., the filename without any preceding directory path and without an extension. It is used inside substitution marks (``) in shell procedures to construct new filenames.

The related command *dirname* deletes the last level from *string* and prints the resulting path on the standard output.

Examples

The following command displays the filename **memos** on the standard output:

```
basename /usr/johnh/memos.old .old
```

The following shell procedure, when invoked with the argument **/usr/src/cmd/cat.c**, compiles the named file and moves the output to a file named **cat** in the current directory:

```
cc $1
mv a.out `basename $1 .c`
```

See Also

dirname(C), *sh*(C)

Name

bc - Invokes a calculator.

Syntax

bc [-c] [-l] [file ...]

Description

bc is an interactive processor for a language that resembles C but provides unlimited precision arithmetic. It takes input from any files given, then reads the standard input. The -l argument stands for the name of an arbitrary precision math library. The syntax for bc programs is as follows: L means the letters a-z, E means expression, S means statement.

Comments:

Enclosed in /* and */

Names:

Simple variables: L

Array elements: L [E]

The words "ibase", "obase", and "scale"

Other operands:

Arbitrarily long numbers with optional sign and decimal point

(E)

sqrt (E)

length (E) Number of significant decimal digits

scale (E) Number of digits right of decimal point

L (E , ... , E)

Additive operators:

+

-

Multiplicative operators:

*

/

% (remainder)

^ (exponentiation)

Unary operators:

++
 -- (prefix and postfix; apply to names)

Relational operators:

==
 <=
 >=
 !=
 <
 >

Assignment operators:

=
 +=
 -=
 *=
 /=
 %=
 ^=

Statements:

E
 { S ; ... ; S }
 if (E) S
 while (E) S
 for (E ; E ; E) S
 null statement
 break
 quit

Function definitions:

```
define L ( L ,..., L ) {
    auto L, ... , L
    S; ... S
    return ( E )
}
```

Functions in `-l` math library:

<code>s(x)</code>	Sine
<code>c(x)</code>	Cosine
<code>e(x)</code>	Exponential
<code>l(x)</code>	Log
<code>a(x)</code>	Arctangent
<code>j(n,x)</code>	Bessel function

All function arguments are passed by value.

The value of a statement that is an expression is printed unless the main operator is an assignment. Either semicolons or newlines may separate statements. Assignment to *scale* influences the number of digits to be retained on arithmetic operations in the manner of *dc(C)*. Assignments to *ibase* or *obase* set the input and output number radix respectively.

The same letter may be used as an array, a function, and a simple variable simultaneously. All variables are global to the program. "Auto" variables are pushed down during function calls. When using arrays as function arguments or defining them as automatic variables, empty square brackets must follow the array name.

bc is actually a preprocessor for *dc(C)*, which it invokes automatically, unless the `-c` (compile only) option is present. If the `-c` option is present, the *dc* input is sent to the standard output instead.

Example

The following defines a function to compute an approximate value of the exponential function:

```
scale = 20
define e(x){
    auto a, b, c, i, s
    a = 1
    b = 1
    s = 1
    for(i=1; 1==1; i++){
        a = a*x
        b = b*i
        c = a/b
        if(c == 0) return(s)
        s = s+c
    }
}
```

The following prints the approximate values of the exponential function of the first ten integers:

```
for(i=1; i<=10; i++) e(i)
```

Files

/usr/lib/lib.bc Mathematical library

dc(C)

The XENIX User's Guide

Notes

A *For* statement must have all three E's.

Quit is interpreted when read, not when executed.

Trigonometric values should be given in radians.

Name

bdiff – Compares files too large for *diff*.

Syntax

bdiff file1 file2 [*n*] [*-s*]

Description

bdiff compares two files, finds lines that are different, and prints them on the standard output. It allows processing of files that are too large for *diff*. *bdiff* splits each file into *n*-line segments, beginning with the first nonmatching lines, and invokes *diff* upon the corresponding segments. The arguments are:

n The number of lines *bdiff* splits each file into for processing. The default value is 3500. This is useful when 3500-line segments are too large for *diff*.

-s Suppresses printing of *bdiff* diagnostics. Note that this does not suppress printing of diagnostics from *diff*.

If *file1* (or *file2*) is a dash (*-*), the standard input is read.

The output of *bdiff* is exactly that of *diff*. Line numbers are adjusted to account for the segmenting of the files, and the output looks as if the files had been processed whole.

Files

/tmp/bd????

See Also

diff(C)

Notes

Because of the segmenting of the files, *bdiff* does not necessarily find a smallest sufficient set of file differences.

Specify the maximum number of lines if the first difference is too far down in the file for *diff* and an error is received.

Name

bfs – Scans big files.

Syntax

bfs [-] name

Description

bfs is like *ed* (C) except that it is read-only and processes much larger files. Files can be up to 1024K bytes and 32K lines, with up to 255 characters per line. *bfs* is usually more efficient than *ed* for scanning a file, since the file is not copied to a buffer. It is most useful for identifying sections of a large file where *csplit* (C) can be used to divide it into more manageable pieces for editing.

Normally, the size of the file being scanned is printed, as is the size of any file written with the *w* command. The optional dash (-) suppresses printing of sizes. Input is prompted for with an asterisk (*) when “P” and RETURN are typed. The “P” acts as a toggle, so prompting can be turned off again by entering another “P” and a RETURN. Note that messages are given in response to errors only if prompting is turned on.

All address expressions described under *ed* are supported. In addition, regular expressions may be surrounded with two symbols other than the standard slash (/) and (?): A greater-than sign (>) indicates downward search without wraparound, and a less-than sign (<) indicates upward search without wraparound. *Note that parentheses and curly braces are special and need to be escaped with a backslash (\).* Since *bfs* uses a different regular expression-matching routine from *ed*, the regular expressions accepted are slightly wider in scope (see *regex* (S)). Differences between *ed* and *bfs* are listed below:

+ A regular expression followed by **+** means *one or more times*. For example, `[0-9]+` is equivalent to `[0-9][0-9]*`.

`\{m\}` `\{m,\}` `\{m,u\}`

Integer values enclosed in `\{ \}` indicate the number of times the preceding regular expression is to be applied. *m* is the minimum number and *u* is a number, less than 256, which is the maximum. If only *m* is present (e.g., `\{m\}`), it indicates the exact number of times the regular expression is to be applied. `\{m,\}` is analogous to `\{m,infinity\}`. The plus (+) and star (*) operations are equivalent to `\{1,\}` and `\{0,\}` respectively.

(...)\$*n* The value of the enclosed regular expression is to be returned. The value will be stored in the (*n*+1)th argument following the subject argument. At most ten enclosed regular expressions are allowed. *regex* makes its assignments unconditionally.

(...) Parentheses are used for grouping. An operator, e.g. *, +, \{\}, can work on a single character or a regular expression enclosed in parenthesis. For example, \a*(cb+)\)*\)\$0.

There is also a slight difference in mark names: only the letters "a" through "z" may be used, and all 26 marks are remembered.

The e, g, v, k, p, q, w, =, ! and null commands operate as described under *ed* except that e doesn't remember filenames and g and v when given no arguments return the line after the line you were on. Commands such as ---, +++-, +++=, -12, and +4p are accepted. Note that 1,10p and 1,10 will both print the first ten lines. The f command only prints the name of the file being scanned; there is no remembered filename. The w command is independent of output diversion, truncation, or crunching (see the xo, xt and xc commands, below). The following additional commands are available:

xf *file*

Further commands are taken from the named *file*. When an end-of-file is reached, an interrupt signal is received, or an error occurs, reading resumes with the file containing the xf. Xf commands may be nested to a depth of 10.

xo [*file*]

Further output from the p and null commands is diverted to the named *file*. If *file* is missing, output is diverted to the standard output. Note that each diversion causes truncation or creation of the file.

: *label*

This positions a *label* in a command file. The *label* is terminated by a newline, and blanks between the : and the start of the *label* are ignored. This command may also be used to insert comments into a command file, since labels need not be referenced.

(. . .)xb/*regular expression*/*label*

A jump (either upward or downward) is made to *label* if the command succeeds. It fails under any of the following conditions:

1. Either address is not between 1 and \$.

2. The second address is less than the first.
3. The regular expression doesn't match at least one line in the specified range, including the first and last lines.

On success, dot (.) is set to the line matched and a jump is made to *label*. This command is the only one that doesn't issue an error message on bad addresses, so it may be used to test whether addresses are bad before other commands are executed. Note that the command

```
xb/^/ label
```

is an unconditional jump.

The **xb** command is allowed only if it is read from somewhere other than a terminal. If it is read from a pipe only a downward jump is possible.

xt *number*

Output from the **p** and null commands is truncated to a maximum of *number* characters. The initial number is 255.

xv[*digit*][*spaces*][*value*]

The variable name is the specified *digit* following the **xv**. **Xv5100** or **xv5 100** both assign the value **100** to the variable **5**. **Xv61,100p** assigns the value **1,100p** to the variable **6**. To reference a variable, put a **%** in front of the variable name. For example, using the above assignments for variables **5** and **6**:

```
1,%5p
1,%5
%6
```

prints the first 100 lines.

```
g/%5/p
```

globally searches for the characters **100** and prints each line containing a match. To escape the special meaning of **%**, a **** must precede it. For example,

```
g/".*\%[cds]/p
```

could be used to match and list lines containing *printf* characters, decimal integers, or strings.

Another feature of the **xv** command is that the first line of output from a XENIX command can be stored into a variable.

The only requirement is that the first character of *value* be a **!**. For example,

```
xv5!cat junk
!rm junk
!echo "%5"
xv6!expr %6 + 1
```

puts the current line in variable **5**, prints it, and increments the variable **6** by one. To escape the special meaning of **!** as the first character of *value*, precede it with a ****. For example,

```
xv7!\!date
```

stores the value **!date** into variable **7**.

xbz *label*

xbn *label*

These two commands test the last saved *return code* from the execution of a XENIX command (*!command*) or nonzero value, respectively, and jump to the specified label. The two examples below search for the next five lines containing the string **size**:

```
xv55
```

Name

cal – Prints a calendar.

Syntax

cal [[month] year]

Description

cal prints a calendar for the specified year. If a month is also specified, a calendar for that month only is printed. If no arguments are specified, the current, previous, and following months are printed, along with the current date and time. The *year* must be a number between 1 and 9999; *month* must be a number between 1 and 12 or enough characters to specify a particular month. For example, **May** must be given to distinguish it from March, but **S** is sufficient to specify September. If only a month string is given, only that month of the current year is printed.

Notes

Beware that “cal 84” refers to the year 84, not 1984.

The calendar produced is that for England and her colonies. Note that England switched from the Julian to the Gregorian calendar in September of 1752, at which time eleven days were excised from the year. To see the result of this switch, try “cal 9 1752”.

Name

calendar – Invokes a reminder service.

Syntax

calendar [-]

Description

calendar consults the file **calendar** in the user's current directory and mails him lines that contain today's or tomorrow's date. Most reasonable month-day dates, such as "Sep. 7," "september 7", and "9/7", are recognized, but not "7 September", "7/12" or "07/12".

On weekends "tomorrow" extends through Monday. Lines that contain the date of a Monday will be sent to the user on the previous Friday. This is not true for holidays.

When an argument is present, *calendar* does its job for every user who has a file **calendar** in his login directory and sends the user the results by *mail* (C). Normally this is done daily, in the early morning, under the control of *cron* (C).

Files

calendar

/usr/lib/calprog To figure out today's and tomorrow's dates

/etc/passwd

/tmp/cal*

See Also

cron(C), mail(C)

Notes

To get reminder service, a user's **calendar** file must have read permission for all.

Name

cat – Concatenates and displays files.

Syntax

cat [-u] [-s] [-v] [-t] [-e] file . . .

Description

cat reads each *file* in sequence and writes it on the standard output. If no input file is given, or if a single dash (-) is given, *cat* reads from the standard input. The options are:

-s
Suppresses warnings about nonexistent files.

-u
Causes the output to be unbuffered.

-v
Causes non-printing characters (with the exception of tabs, new-lines, and form feeds) to be displayed. Control characters are displayed as “^X” (Ctrl-X); the DEL character (octal 0177) is printed as “^?”. Non-ASCII characters (with the high bit set) are printed as “M -x,” where x is the character specified by the seven low order bits.

-t Causes a tab to be printed as “^I.” This option is ignored if the **-v** option is not specified.

-e
Causes a “\$” character to be printed at the end of each line (prior to the new-line). This option is ignored if the **-v** option is not set.

No input file may have the same name as the output file unless it is a special file.

Examples

The following example displays *file* on the standard output:

```
cat file
```

The following example concatenates *file1* and *file2* and places the result in *file3*:

```
cat file1 file2 >file3
```

The following example concatenates *file1* and appends it to *file2*:

```
cat file1 >> file2
```

See Also

cp(C), pr(C)

Warning

Command lines such as:

```
cat file 1 file2 > file1
```

will cause the original data in *file1* to be lost; therefore, you must be careful when using special shell characters.

Name

`cd` – Changes working directory.

Syntax

`cd [directory]`

Description

If specified, *directory* becomes the new working directory; otherwise the value of the shell parameter `$HOME` is used. The process must have search (execute) permission in all directories (components) specified in the full pathname of *directory*.

Because a new process is created to execute each command, *cd* would be ineffective if it were written as a normal command; therefore, it is recognized and executed by the shell.

If the shell is reading its commands from a terminal, and the specified directory does not exist (or some component cannot be searched), spelling correction is applied to each component of *directory*, in a search for the “correct” name. The shell then asks whether or not to try and change directory to the corrected directory name; an answer of *n* means “no”, and anything else is taken as “yes”.

Notes

Wildcard designators do not work with the `cd` command.

See Also

`pwd(C)`, `sh(C)`, `chdir(S)`

Name

chgrp – Changes group ID.

Syntax

chgrp *group file ...*

Description

chgrp changes the group ID of each *file* to *group*. The group may be either a decimal group ID or a group name found in the file */etc/group*.

Files

/etc/passwd

/etc/group

See Also

chown(C), chown(S), passwd(M), group(M)

Notes

Only the owner or the super-user can change the group ID of a file.

Name

chmod – Changes the access permissions of a file or directory.

Syntax

chmod *mode file ...*

chmod [*who*] += [permission ...] *file ...*

Description

The *chmod* command changes the access permissions (or *mode*) of a specified file or directory. It is used to control file and directory access by users other than the owner and super-user. The *mode* may be an expression composed of letters and operators (called *symbolic mode*), or a number (called *absolute mode*).

A *chmod* command using *symbolic mode* has the form:

chmod [*who*] += [permission ...] *filename*

In place of *who* you can use one or any combination of the following letters:

- a** Stands for “all users”. If *who* is not indicated on the command line, **a** is the default. The definition of “all users” depends on the user’s *umask*. See *umask*(C).
- g** Stands for “group”, all users who have the same group ID as the owner of the file or directory.
- o** Stands for “others”, all users on the system.
- u** Stands for “user”, the owner of the file or directory.

The operators are:

- +** Adds permission
- Removes permission
- =** Assigns the indicated permission and removes all other permissions (if any) for that *who*. If no permission is assigned, existing permissions are removed.

Permissions can be any combination of the following letters:

- x** Execute (search permission for directories)

- r Read
- w Write
- s Sets owner or group ID on execution of the file to that of the owner of the file. The mode "u+s" sets the user ID bit for the file. The mode "g+s" sets the group ID bit. Other combinations have no effect.
- t Saves text in memory upon execution. ("Sticky bit", see *chmod(S)*). Only the mode "u+t" sets the sticky bit. All other combinations have no effect. This mode can only be set by the super-user.

Multiple symbolic modes may be given, separated by commas, on a single command line. See the following Examples section for sample permission settings.

A *chmod* command using *absolute mode* has the form:

chmod mode filename

where *mode* is an octal number constructed by performing logical OR on the following:

4000	Set user ID on execution
2000	Set group ID on execution
1000	Sets the sticky bit (see <i>chmod(S)</i>)
0400	Read by owner
0200	Write by owner
0100	Execute (search in directory) by owner
0040	Read by group
0020	Write by group
0010	Execute (search in directory) by group
0004	Read by others
0002	Write by others
0001	Execute (search in directory) by others
0000	No permissions

Examples*Symbolic Mode*

The following command gives all users execute permission for *file*:

```
chmod +x file
```

The following command removes read and write permission for group and others from *file*:

```
chmod go-rw file
```

The following command gives other users read and write permission for *file*:

```
chmod o+rw file
```

The following command gives read permission to group and other:

```
chmod g+r,o+r file
```

Absolute Mode

The following command gives all users read, write and execute permission for *file*:

```
chmod 0777 file
```

The following command gives read and write permission to all users for *file*:

```
chmod 0666 file
```

The following command gives read and write permission to the owner of *file* only:

```
chmod 0600 file
```

See Also

ls(C), chmod(S)

Notes

The user ID, group ID and sticky bit settings are only useful for binary executable files. They have no effect on shell scripts.

Name

chown - Changes owner ID.

Syntax

chown owner file ...

Description

chown changes the owner ID of the *files* to *owner*. The owner may be either a decimal user ID or a login name found in the file */etc/passwd*.

Files

/etc/passwd

/etc/group

See Also

chgrp(C), chown(S), group(M), passwd(M)

Notes

Only the owner or the super-user can change a file's owner or group ID.

Name

chroot – Changes root directory for command.

Syntax

chroot newroot command

Description

The given command is executed relative to the new root. The meaning of any initial slashes (*/*) in pathnames is changed for a command and any of its children to *newroot*. Furthermore, the initial working directory is *newroot*.

Notice that:

chroot newroot command >x

creates the file *x* relative to the original root, not the new one.

This command is restricted to the super-user.

The new root pathname is always relative to the current root even if a *chroot* is currently in effect. The *newroot* argument is relative to the current root of the running process. Note that it is not possible to change directories to what was formerly the parent of the new root directory; i.e., the *chroot* command supports the new root as an absolute root for the duration of the *command*. This means that *“/..”* is always equivalent to *“/”*.

See Also

chdir(S)

Notes

Exercise extreme caution when referencing special files in the new root file system.

command must be under *newroot* or *command* is reported:
command: not found

Name

clockrate – Changes clock rate.

Syntax

/etc/clockrate frequency

Description

/etc/clockrate alters the interrupt timer clock frequency (different from the CPU clock frequency) to bring the system clock in sync with the computer's clock. This frequency is expressed in Megahertz (megaHZ) and can be found in the computer's hardware reference manual.

To set a new clockrate to 1.22878, for example, type:

```
# /etc/clockrate 1.22878
```

/etc/clockrate is a compiled "C" program, which modifies the kernel found in */xenix*.

/etc/clockrate only needs to be run once, unless you reinstall the XENIX distribution floppies.

Files

/etc/clockrate

Notes

Your computer may not be able to change the clockrate of your computer with this utility.

Name

clri - Clears inode.

Syntax

/etc/clri file-system i-number ...

Description

clri writes zeros on the 64 bytes occupied by the inode numbered *i-number*. *File-system* must be a special filename referring to a device containing a file system. After *clri* is executed, any blocks in the affected file will show up as "missing" if the file system is checked with *fsck(C)*. Use *clri* only in emergencies and exercise extreme care.

Read and write permission is required on the specified *file-system* device. The inode becomes allocatable.

The primary purpose of this routine is to remove a file which, for some reason, does not appear in a directory. If you use *clri* to destroy an inode which does appear in a directory, track down the entry and remove it. Otherwise, when the inode is reallocated to some new file, the old entry will still point to this file. At that point removing the old entry will destroy the new file. The new entry will again point to an unallocated inode, so the whole cycle is likely to be repeated again and again.

See Also

fsck(C), *ncheck(C)*

Notes

If the file is open, *clri* is likely to be ineffective.

Name

cmchk – Reports hard disk block size.

Syntax

cmchk

Description

Reports the hard disk block size (BSIZE) in bytes.

Name

cmp – Compares two files.

Syntax

cmp [-l] [-s] file1 file2

Description

cmp compares two files and, if they are different, displays the byte and line number of the differences. If *file1* is `-`, the standard input is used.

The options are:

- `-l` Prints the byte number (decimal) and the differing bytes (octal) for each difference.
- `-s` Returns an exit code only, 0 for identical files, 1 for different files and 2 for an inaccessible or missing file.

This command should be used to compare binary files; use *diff* (C) or *diff3* (C) to compare text files.

See Also

comm(C), diff(C), diff3(C)

Diagnostics

Exit code 0 is returned for identical files, 1 for different files, and 2 for an inaccessible or missing argument.

Name

`comm` - Selects or rejects lines common to two sorted files.

Syntax

`comm [- [123]] file1 file2`

Description

`comm` reads *file1* and *file2*, which should be ordered in ASCII collating sequence (see `sort (C)`), and produces a three-column output: lines only in *file1*; lines only in *file2*; and lines in both files. The filename `-` means the standard input.

Flags 1, 2, or 3 suppress printing of the corresponding column. Thus `comm -12` prints only the lines common to the two files; `comm -23` prints only lines in the first file but not in the second; `comm -123` is a no-op.

See Also

`cmp(C)`, `diff(C)`, `sort(C)`, `uniq(C)`

Name

copy – Copies groups of files.

Syntax

copy [option] ... source ... dest

Description

The *copy* command copies the contents of directories to another directory. It is possible to copy whole file systems since directories are made when needed.

If files, directories, or special files do not exist at the destination, then they are created with the same modes and flags as the source. In addition, the super-user may set the user and group ID. The owner and mode are not changed if the destination file exists.

Note that there may be more than one source directory. If so, the effect is the same as if the *copy* command had been issued for each source directory with the same destination directory for each copy.

Options do not have to be given as separate arguments, and may appear in any order, even after the other arguments. The options are:

- a** Asks the user before attempting a copy. If the response does not begin with a “y”, then a copy is not done. option.
- l** Uses links instead whenever they can be used. Otherwise a copy is done. Note that links are never done for special files or directories.
- n** Requires the destination file to be new. If not, then the *copy* command does not change the destination file. The **-n** flag is meaningless for directories. For special files an **-n** flag is assumed (i.e., the destination of a special file must not exist).
- o** If set then every file copied has its owner and group set to those of the source. If not set, then the file's owner is the user who invoked the program.
- m** If set, then every file copied has its modification time and access time set to that of the source. If not set, then the modification time is set to the time of the copy.

- r** If set, then every directory is recursively examined as it is encountered. If not set then any directories that are found are ignored.
- ad** Asks the user whether a **-r** flag applies when a directory is discovered. If the answer does not begin with a "y", then the directory is ignored.
- v** If the verbose option is set messages are printed that reveal what the program is doing.

Arguments to *copy* are:

- source** This may be a file, directory or special file. It must exist. If it is not a directory, then the results of the command are the same as for the *cp* command.
- dest** The destination must be either a file or directory that is different from the source.

If the source and destination are anything but directories, then *copy* acts just like a *cp* command. If both are directories, then *copy* copies each file into the destination directory according to the flags that have been set.

Examples

This command line verbosely copies all files in the current directory to */tmp/food*:

```
copy -v . /tmp/food
```

The next command line copies all files, except for those that begin with a period (.), and copies the immediate contents of any child directories:

```
copy * /tmp/logic
```

This command is the same as the previous one, except that it recursively examines all subdirectories, and it sets group and ownership permissions on the destination files to be the same as the source files:

```
copy -ro * /tmp/logic
```

Notes

Special device files can be copied. When they are copied, any data associated with the specified device is *not* copied.

Name

cp – Copies files.

Syntax

cp file1 file2

cp files directory

Description

There are two ways to use the *cp* command. With the first way, *file1* is copied to *file2*. Under no circumstance can *file1* and *file2* be identical. With the second way, *directory* is the location of a directory into which one or more *files* are copied.

See Also

copy(C), cpio(C), ln(C), mv(C), rm(C), chmod(S)

Notes

Special device files can be copied. If the file is a named pipe, then the data in the pipe is copied to a regular file. Similarly, if the file is a device, then the file is read until the end-of-file is reached, and that data is copied to a regular file. It is illegal to copy a directory to a file.

Name

`cpio` – Copies file archives in and out.

Syntax

`cpio -o [acBv]`

`cpio -i [Bcdmrtuv] [patterns]`

`cpio -p [adlmrv] directory`

Description

`cpio -o` (copy out) reads the standard input to obtain a list of pathnames and copies those files onto the standard output together with pathname and status information.

`cpio -i` (copy in) extracts from the standard input (which is assumed to be the product of a previous `cpio -o`) the names of files selected by zero or more *patterns* given in the name-generating notation of *sh* (C). In *patterns*, the special characters `?`, `*`, and `[...]` match the slash (`/`) character. The default for *patterns* is `*` (i.e., select all files).

Remember to escape special characters to prevent expansion by the shell.

`cpio -p` (pass) copies out and in during a single operation. Destination pathnames are interpreted relative to the named *directory*.

The meanings of the available options are:

- a** Resets access times of input files after they have been copied.
- B** Blocks input/output 5,120 bytes to the record (does not apply to the *pass* option; meaningful only with data directed to or from raw devices).
- d** Directories are created as needed.
- c** Writes header information in ASCII character form for portability.
- r** Interactively renames files. If the user types a null line, the file is skipped.

- t** Prints a table of contents of the input. No files are created.
- u** Copies unconditionally (normally an older file will not replace a newer file with the same name).
- v** Verbose: causes a list of filenames to be printed. When used with the **-t** option, the table of contents looks like the output of an **ls -l** command (see **ls (C)**).
- l** Whenever possible, links files rather than copying them. Usable only with the **-p** option.
- m** Retains previous file modification time. This option is ineffective on directories that are being copied.

Examples

The first example below copies the contents of a directory into an archive; the second duplicates a directory hierarchy:

```
ls | cpio -o >/dev/fd
cd olddir
find . -print | cpio -pdl newdir
```

Or:

```
find . -print | cpio -oB >/dev/rfd
```

See Also

ar(CP), find(C), cpio(F)

Notes

Pathnames are restricted to 128 characters. If there are too many unique linked files, the program runs out of memory to keep track of them and thereafter linking information is lost. Only the super-user can copy special files.

Name

cron - Executes commands at specified times.

Syntax

```
/etc/cron
crontab [file]
crontab -r
crontab -l
```

Description

cron is the clock daemon that executes commands at specified dates and times according to the instructions in the files located in */usr/spool/cron/crontabs*. Regularly scheduled commands can be specified according to instructions found in crontab files; users can submit their own crontab file via the *crontab* command. Commands which are to be executed only once may be submitted via the *at* command. Because *cron* never exits, it should be executed only once. This is best done by running *cron* from the initialization process through the file */etc/rc*.

crontab copies the specified file, or standard input if no file is specified, into a directory that holds all users' crontabs. The *-crontab* file in the *crontabs* directory is given the user's login name. The *-r* option removes a user's crontab from the crontab directory. *crontab -l* will list the crontab file for the invoking user.

A user is permitted to use *crontab* if their name appears in the file */usr/lib/cron/cron.allow*. If that file does not exist, the file */usr/lib/cron/cron.deny* is checked to determine if the user should be denied access to *crontab*. If neither file exists, only root is allowed to submit a job. Global usage is permitted by the existence of an empty *cron.deny* file. *cron.deny* is checked only if *cron.allow* does not exist. The allow/deny files consist of one user name per line.

The *crontabs* files consist of lines of six fields each. The fields are separated by spaces or tabs. The first five are integer patterns that specify the minute (0-59), hour (0-23), day of the month (1-31), month of the year (1-12), and day of the week (0-6, with 0=Sunday). Each of these patterns may contain:

- A number in the (respective) range indicated above
- Two numbers separated by a minus (indicating an inclusive range)

- A list of numbers separated by commas (meaning all of these numbers)
- An asterisk (meaning all legal values)

Note that the specification of days may be made by two fields (day of the month and day of the week). If both are specified as a list of elements, both are adhered to. For example, `0 0 1,15 * 1` would run a command on the first and fifteenth of each month, as well as on every Monday. To specify days by only one field, the other field should be set to `*` (for example, `0 0 * * 1` would run a command only on Mondays).

The sixth field is a string that is executed by the shell at the specified time(s). A `%` in this field is translated into a newline character. Only the first line (up to a `%` or end-of-line) of the command field is executed by the shell. The other lines are made available to the command as standard input.

The shell is invoked from your `$HOME` directory with an `arg0` of `sh`. Users who desire to have their `.profile` executed must explicitly do so in the crontab file. `cron` supplies a default environment for every shell, defining `HOME`, `LOGNAME`, `SHELL` (`=/bin/sh`), and `PATH` (`=:/bin:/usr/bin:/usr/sbin`).

`cron` examines the `crontabs` directory periodically to see if it has changed; if it has, `cron` reads it. Thus it takes only a short while for entries to become effective.

Examples

An example `crontabs` file follows:

```
30 4 * * *    /etc/sa -s > /dev/null
0 4 * * *     calendar -
15 4 * * *    find /usr/preserve -mtime +7 -a -exec rm -f {} ;
30 4 1 1 1    /usr/lib/uucp/uuclean
40 4 * * *    find / -name '#*' -atime +3 -exec rm -f {} ;
0,10,20,30,40,50 * * * */etc/dmesg - >>>/usr/adm/messages
1,21,41 * * * * (echo -n ' '; date; echo ) >/dev/console
```

A history of all actions by `cron` can be recorded in `/usr/lib/cron/log`. This logging occurs only if the variable `CRON-LOG` in `/etc/default/cron` is set to `YES`. By default this value is set to `NO` and no logging occurs. If logging should be turned on, be sure to monitor the size of `/usr/lib/cron/log` so that it doesn't unreasonably consume disk space.

Files

/usr/lib/cron	main cron directory
/usr/spool/cron/crontabs/*	spool area
/usr/lib/cron/log	accounting information
/usr/lib/cron/cron.allow	list of allowed users
/usr/lib/cron/cron.deny	list of denied users
/usr/lib/cron/.proto	cron environment information
/etc/default/cron	cron logging default information

See Also

at(C), sh(C)

Notes

cron reads the files in the **crontabs** directory only when there is a change, but it reads the in-core version of the tables periodically.

Users should remember to redirect the standard output and standard error of their commands! If this is not done, any generated output or errors will be mailed to the user.

Name

`csh` – Invokes a shell command interpreter with C-like syntax.

Syntax

`csh [- cefinstvVxX] [arg ...]`

Description

`csh` is a command language interpreter. It begins by executing commands from the file `.cshrc` in the home directory of the invoker. If this is a login shell, it also executes commands from the file `.login` there. In the normal case, the shell begins reading commands from the terminal, prompting with `%`. Processing of arguments and the use of the shell to process files containing command scripts will be described later.

The shell then repeatedly performs the following actions: a line of command input is read and broken into *words*. This sequence of words is placed on the command history list and then parsed. Finally, each command in the current line is executed.

When a login shell terminates, it executes commands from the file `.logout` in the user's home directory.

Lexical structure

The shell splits input lines into words at blanks and tabs with the following exceptions. The characters `&`, `|`, `;`, `<`, `>`, `(`, `)`, form separate words. If doubled in `&&`, `||`, `<<`, or `>>`, these pairs form single words. These parser metacharacters may be made part of other words, or prevented their special meaning, by preceding them with `\`. A newline preceded by a `\` is equivalent to a blank.

In addition, strings enclosed in matched pairs of quotations, `'`, ``` or `"`, form parts of a word; metacharacters in these strings, including blanks and tabs, do not form separate words. These quotations have semantics to be described subsequently. Within pairs of `\` or `"` characters, a newline preceded by a `\` gives a true newline character.

When the shell's input is not a terminal, the character `#` introduces a comment which continues to the end of the input line. It does not have this special meaning when preceded by `\` and placed inside the quotation marks `'`, ```, and `"`.

Commands

A simple command is a sequence of words, the first of which specifies the command to be executed. A simple command or a sequence of simple commands separated by `|` characters forms a pipeline. The output of each command in a pipeline is connected to the input of the next. Sequences of pipelines may be separated by `;`, and are then executed sequentially. A sequence of pipelines may be executed without waiting for it to terminate by following it with a `&`. Such a sequence is automatically prevented from being terminated by a hangup signal; the *nohup* command need not be used.

Any of the above may be placed in parentheses to form a simple command (which may be a component of a pipeline, etc.) It is also possible to separate pipelines with `||` or `&&` indicating, as in the C language, that the second is to be executed only if the first fails or succeeds respectively. (See *Expressions*.)

Substitutions

The following sections describe the various transformations the shell performs on the input in the order in which they occur.

History Substitutions

History substitutions can be used to reintroduce sequences of words from previous commands, possibly performing modifications on these words. Thus, history substitutions provide a generalization of a *redo* function.

History substitutions begin with the character `!` and may begin **anywhere** in the input stream if a history substitution is not already in progress. The `!` may be preceded by a `\` to prevent its special meaning; a `!` is passed unchanged when it is followed by a blank, tab, newline, `=`, or `(`. History substitutions may also occur when an input line begins with `^`. This special abbreviation will be described later.

Any input line which contains history substitution is echoed on the terminal before it is executed as it could have been entered without history substitution.

Commands input from the terminal which consist of one or more words are saved on the history list, the size of which is controlled by the *history* variable. The previous command is always retained. Commands are numbered sequentially from 1.

For example, enter the command:

```
history
```

Now, consider the following output from the history command:

```
9 write michael
10 ex write.c
11 cat oldwrite.c
12 diff *write.c
```

The commands are shown with their event numbers. It is not usually necessary to use event numbers, but the current event number can be made part of the prompt by placing a ! in the prompt string.

With the current event 13 we can refer to previous events by event number !11, relatively as in !-2 (referring to the same event), by a prefix of a command word as in !d for event 12 or !w for event 9, or by a string contained in a word in the command as in !?mic? also referring to event 9. These forms, without further modification, simply reintroduce the words of the specified events, each separated by a single blank. As a special case !! refers to the previous command; thus !! alone is essentially a *redo*. The form !# references the current command (the one being entered). It allows a word to be selected from further left in the line, to avoid retyping a long name, as in !#:1.

To select words from an event, we can follow the event specification by a : and a designator for the desired words. The words of an input line are numbered from 0, the first (usually command) word being 0, the second word (first argument) being 1, and so on. The basic word designators are:

0 First (command) word

n nth argument

^ First argument, i.e. 1

\$ Last argument

% Word matched by (immediately preceding) ?s ? search

x-y
Range of words

-y Abbreviates 0-y

* Abbreviates ^-\$, or nothing if only 1 word in event

x * Abbreviates *x* - \$

x - Like *x* * but omitting word \$

The : separating the event specification from the word designator can be omitted if the argument selector begins with a ^, \$, *, - or %. After the optional word designator, a sequence of modifiers can be placed, each preceded by a :. The following modifiers are defined:

h Removes a trailing pathname component

r Removes a trailing .xxx component

s/*l*/*r*/

Substitutes *l* for *r*

t Removes all leading pathname components

& Repeats the previous substitution

g Applies the change globally, prefixing the above

p Prints the new command but does not execute it

q Quotes the substituted words, preventing substitutions

x Like q, but breaks into words at blanks, tabs, and newlines

Unless preceded by a g, the modification is applied only to the first modifiable word. In any case it is an error for no word to be applicable.

The left sides of substitutions are not regular expressions in the sense of the editors, but rather strings. Any character may be used as the delimiter in place of /; a \ quotes the delimiter into the *l* and *r* strings. The character & in the right side is replaced by the text from the left. A \ quotes & also. A null *l* uses the previous string either from a *l* or from a contextual scan string *s* in *!s*?. The trailing delimiter in the substitution may be omitted if a newline follows immediately as may the trailing ? in a contextual scan.

A history reference may be given without an event specification, e.g., !\$. In this case the reference is to the previous command unless a previous history reference occurred on the same line in which case this form repeats the previous reference. Thus *!foo?^!*\$ gives the first and last arguments from the command matching *?foo?*.

A special abbreviation of a history reference occurs when the first nonblank character of an input line is a ^. This is equivalent to *!s^*, providing a convenient shorthand for substitutions on the text of

the previous line. Thus `^lb^lib` fixes the spelling of `lib` in the previous command. Finally, a history substitution may be surrounded with `{` and `}` if necessary to insulate it from the characters that follow. Thus, after `ls -ld ~paul` we might do `!{!}a` to do `ls -ld ~paula`, while `!!a` would look for a command starting `la`.

Quotations With ' and "

The quotation of strings by `'` and `"` can be used to prevent all or some of the remaining substitutions. Strings enclosed in `'` are prevented any further interpretation. Strings enclosed in `"` are variable and command expansion may occur.

In both cases, the resulting text becomes (all or part of) a single word; only in one special case (see *Command Substitution* below) does a `"` quoted string yield parts of more than one word; `'` quoted strings never do.

Alias Substitution

The shell maintains a list of aliases which can be established, displayed and modified by the *alias* and *unalias* commands. After a command line is scanned, it is parsed into distinct commands and the first word of each command, left-to-right, is checked to see if it has an alias. If it does, then the text which is the alias for that command is reread with the history mechanism available as though that command were the previous input line. The resulting words replace the command and argument list. If no reference is made to the history list, then the argument list is left unchanged.

Thus if the alias for `ls` is `ls -l` the command `"ls /usr"` would map to `"ls -l /usr"`. Similarly if the alias for `lookup` was `"grep ^/etc/passwd"` then `"lookup bill"` would map to `"grep bill /etc/passwd"`.

If an alias is found, the word transformation of the input text is performed and the aliasing process begins again on the reformed input line. Looping is prevented if the first word of the new text is the same as the old by flagging it to prevent further aliasing. Other loops are detected and cause an error.

Note that the mechanism allows aliases to introduce parser metasyntax. Thus we can alias print `"pr \!* | lpr"` to make a command that paginates its arguments to the lineprinter.

There are four *cs**h* aliases distributed with the XENIX System V *cs**h*. These are **pushd**, **popd**, **swapped**, and **flipd**. These aliases maintain a directory stack.

pushd *dir*

Pushes the current directory onto the top of the directory stack, changes to the directory *dir*.

popd

Changes to the directory at the top of the stack, then removes (pops) the top directory from the stack, and announces the current directory.

swapd

Swaps the top two directories on the stack. The directory on the top becomes the second to the top, and the second to the top directory becomes the top directory.

flipd

Flips between two directories, the current directory and the top directory on the stack. If you are currently in *dir1*, and *dir2* is on the top of the stack, when **flipd** is invoked, you change to *dir2* and *dir1* is replaced as the top directory on the stack. When **flipd** is again invoked, you change to *dir1* and *dir2* is again the top directory on the stack.

Variable Substitution

The shell maintains a set of variables, each of which has a list of zero or more words as its value. Some of these variables are set by the shell or referred to by it. For instance, the *argv* variable is an image of the shell's argument list, and words of this variable's value are referred to in special ways.

The values of variables may be displayed and changed by using the *set* and *unset* commands. Of the variables referred to by the shell a number are toggles; the shell does not care what their value is, only whether they are set or not. For instance, the *verbose* variable is a toggle which causes command input to be echoed. The setting of this variable results from the *-v* command line option.

Other operations treat variables numerically. The at-sign (@) command permits numeric calculations to be performed and the result assigned to a variable. However, variable values are always represented as (zero or more) strings. For the purposes of numeric operations, the null string is considered to be zero, and the second and subsequent words of multiword values are ignored.

After the input line is aliased and parsed, and before each command is executed, variable substitution is performed, keyed by dollar sign (\$) characters. This expansion can be prevented by preceding the dollar sign with a backslash (\) except within double quotation marks (") where it *always* occurs, and within single quotation marks (') where it *never* occurs. Strings quoted by back quotation marks (`) are interpreted later (see *Command substitution* below) so

dollar sign substitution does not occur there until later, if at all. A dollar sign is passed unchanged if followed by a blank, tab, or end-of-line.

Input and output redirections are recognized before variable expansion, and are variable expanded separately. Otherwise, the command name and entire argument list are expanded together. It is thus possible for the first (command) word to generate more than one word, the first of which becomes the command name, and the rest of which become arguments.

Unless enclosed in double quotation marks or given the :q modifier, the results of variable substitution may eventually be command and filename substituted. Within double quotation marks (") a variable whose value consists of multiple words expands to a portion of a single word, with the words of the variable's value separated by blanks. When the :q modifier is applied to a substitution, the variable expands to multiple words with each word separated by a blank and quoted to prevent later command or filename substitution.

The following sequences are provided for introducing variable values into the shell input. Except as noted, it is an error to reference a variable which is not set.

`$name`

`${name}`

Are replaced by the words of the value of variable *name*, each separated by a blank. Braces insulate *name* from following characters which would otherwise be part of it. Shell variables have names consisting of up to 20 letters, digits, and underscores.

If *name* is not a shell variable, but is set in the environment, then that value is returned (but : modifiers and the other forms given below are not available in this case).

`$name[selector]`

`${name[selector]}`

May be used to select only some of the words from the value of *name*. The selector is subjected to \$ substitution and may consist of a single number or two numbers separated by a -. The first word of a variable's value is numbered 1. If the first number of a range is omitted it defaults to 1. If the last member of a range is omitted it defaults to \$#name. The selector * selects all words. It is not an error for a range to be empty if the second argument is omitted or in range.

`$#name`

`${#name}`

Gives the number of words in the variable. This is useful for later use in a [selector].

`$0` Substitutes the name of the file from which command input is being read. An error occurs if the name is not known.

`$number`
`${number}`
 Equivalent to `$argv[number]`.

`$*` Equivalent to `$argv[*]`.

The modifiers `:h`, `:t`, `:r`, `:q` and `:x` may be applied to the substitutions above as may `:gh`, `:gt` and `:gr`. If braces `{ }` appear in the command form then the modifiers must appear within the braces. Only one `:` modifier is allowed on each `$` expansion.

The following substitutions may not be modified with `:` modifiers.

`$?name`
`${?name}`
 Substitutes the string 1 if name is set, 0 if it is not.

`$?0` Substitutes 1 if the current input filename is known, 0 if it is not.

`$$` Substitutes the (decimal) process number of the (parent) shell.

Command and Filename Substitution

Command and filename substitution are applied selectively to the arguments of built-in commands. This means that portions of expressions which are not evaluated are not subjected to these expansions. For commands which are not internal to the shell, the command name is substituted separately from the argument list. This occurs very late, after input-output redirection is performed, and in a child of the main shell.

Command Substitution

Command substitution is indicated by a command enclosed in back quotation marks. The output from such a command is normally broken into separate words at blanks, tabs and newlines, with null words being discarded, this text then replacing the original string. Within double quotation marks, only newlines force new words; blanks and tabs are preserved.

In any case, the single final newline does not force a new word. Note that it is possible for a command substitution to yield only part of a word, even if the command outputs a complete line.

Filename Substitution

If a word contains any of the characters *, ?, [or { or begins with the character ~, then that word is a candidate for filename substitution, also known as globbing. This word is then regarded as a pattern, and replaced with an alphabetically sorted list of filenames which match the pattern. In a list of words specifying filename substitution it is an error for no pattern to match an existing filename, but it is not required for each pattern to match. Only the meta-characters *, ?, and [imply pattern matching, the characters ~ and { being more akin to abbreviations.

In matching filenames, the character . at the beginning of a filename or immediately following a /, as well as the character / must be matched explicitly. The character * matches any string of characters, including the null string. The character ? matches any single character. The sequence [square brackets] matches any one of the characters enclosed. Within [square brackets], a pair of characters separated by - matches any character lexically between the two.

The character ~ at the beginning of a filename is used to refer to home directories. Standing alone, it expands to the invoker's home directory as reflected in the value of the variable *home*. When followed by a name consisting of letters, digits and - characters the shell searches for a user with that name and substitutes their home directory; thus ~ken might expand to /usr/ken and ~ken/chmach to /usr/ken/chmach. If the character ~ is followed by a character other than a letter or / or appears not at the beginning of a word, it is left unchanged.

The metanotation a{b,c,d}e is a shorthand for abe ace ade. Left to right order is preserved, with results of matches being sorted separately at a low level to preserve this order. This construct may be nested. Thus ~source/s1/{oldls,ls}.c expands to /usr/source/s1/oldls.c /usr/source/s1/ls.c, whether or not these files exist, assuming that if the home directory for source is /usr/source. Similarly ../{memo,*box} might expand to ../memo ../box ../mbox. (Note that memo was not sorted with the results of matching *box.) As a special case {, } and {} are passed unchanged.

Input/Output

The standard input and standard output of a command may be redirected with the following syntax:

< name

Opens file *name* (which is first variable, command and filename expanded) as the standard input.

<< word

Reads the shell input up to a line which is identical to *word*. *Word* is not subjected to variable, filename or command substitution, and each input line is compared to *word* before any substitutions are done on this input line. Unless a quoting backslash, double, or single quotation mark, or a back quotation mark appears in *word*, variable and command substitution is performed on the intervening lines, allowing \ to quote \$, \ and `. Commands which are substituted have all blanks, tabs, and newlines preserved, except for the final newline which is dropped. The resulting text is placed in an anonymous temporary file which is given to the command as standard input.

> name

>! name

>& name

>&! name

The file *name* is used as standard output. If the file does not exist, then it is created; if the file exists, it is truncated, and its previous contents are lost.

If the variable *noclobber* is set, then the file must not already exist or it must be a character special file (e.g., a terminal or /dev/null) or an error results. This helps prevent accidental destruction of files. In this case, the ! forms can be used and suppress this check.

The forms involving & route the diagnostic output into the specified file as well as the standard output. *Name* is expanded in the same way as < input filenames are.

>> name

>>& name

>>! name

>>&! name

Uses file *name* as standard output like > but places output at the end of the file. If the variable *noclobber* is set, then it is an error for the file not to exist unless one of the ! forms is given. Otherwise similar to >.

If a command is run detached (followed by &) then the default standard input for the command is the empty file /dev/null. Otherwise, the command receives the environment in which the shell was invoked as modified by the input-output parameters and the presence of the command in a pipeline. Thus, unlike some previous shells, commands run from a file of shell commands have no access to the text of the commands by default; rather they receive the original standard input of the shell. The << mechanism should be used to present inline data. This permits shell command scripts to function as components of pipelines and allows the shell to block read its input.

Diagnostic output may be directed through a pipe with the standard output. Simply use the form `|&` rather than just `|`.

Expressions

A number of the built-in commands (to be described later) take expressions, in which the operators are similar to those of C, with the same precedence. These expressions appear in the `@`, `exit`, `if`, and `while` commands. The following operators are available:

| | && | ^ & == != <= >= < > << >>
+ - * / % ! ~ ()

Here the precedence increases to the right, `==` and `!=`, `<=`, `>=`, `<`, and `>`, `<<` and `>>`, `+` and `-`, `*` / and `%` being, in groups, at the same level. The `==` and `!=` operators compare their arguments as strings, all others operate on numbers. Strings which begin with 0 are considered octal numbers. Null or missing arguments are considered 0. The result of all expressions are strings, which represent decimal numbers. It is important to note that no two components of an expression can appear in the same word; except when adjacent to components of expressions which are syntactically significant to the parser (`&` `|` `<` `>` `(` `)`) they should be surrounded by spaces.

Also available in expressions as primitive operands are command executions enclosed in `{` and `}` and file enquiries of the form `-l` name where `l` is one of:

r	Read access
w	Write access
x	Execute access
e	Existence
o	Ownership
z	Zero size
f	Plain file
d	Directory

The specified name is command and filename expanded, then tested to see if it has the specified relationship to the real user. If the file does not exist or is inaccessible then all enquiries return false, i.e. 0. Command executions succeed, returning true, i.e. 1, if the command exits with status 0, otherwise they fail, returning false, i.e. 0. If more detailed status information is required then the command should be executed outside of an expression and the variable `status` examined.

Control Flow

The shell contains a number of commands which can be used to regulate the flow of control in command files (shell scripts) and (in limited but useful ways) from terminal input. These commands all

operate by forcing the shell to reread or skip in its input and, due to the implementation, restrict the placement of some of the commands.

The *foreach*, *switch*, and *while* statements, as well as the *if-then-else* form of the *if* statement require that the major keywords appear in a single simple command on an input line as shown below.

If the shell's input is not seekable, the shell buffers up input whenever a loop is being read and performs seeks in this internal buffer to accomplish the rereading implied by the loop. (To the extent that this allows, backward goto commands will succeed on non-seekable inputs.)

Built-In Commands

Built-in commands are executed within the shell. If a built-in command occurs as any component of a pipeline except the last, then it is executed in a subshell.

alias

alias name

alias name wordlist

The first form prints all aliases. The second form prints the alias for *name*. The final form assigns the specified *wordlist* as the alias of *name*; *wordlist* is command and filename substituted. *Name* is not allowed to be *alias* or *unalias*

break

Causes execution to resume after the *end* of the nearest enclosing *foreach* or *while* statement. The remaining commands on the current line are executed. Multilevel breaks are thus possible by writing them all on one line.

breaksw

Causes a break from a *switch*, resuming after the *endsw*.

case label:

A label in a *switch* statement as discussed below.

cd

cd name

chdir

chdir name

Changes the shell's working directory to directory *name*. If no argument is given, it then changes to the home directory of the user. If *name* is not found as a subdirectory of the current directory (and does not begin with */*, *./*, or *../*), then each component of the variable *cdpath* is checked to see if it has a subdirectory *name*. Finally, if all else fails but *name* is a shell variable whose value begins with */*, then this is tried to

see if it is a directory.

continue

Continues execution of the nearest enclosing *while* or *foreach*. The rest of the commands on the current line are executed.

default:

Labels the default case in a *switch* statement. The default should come after all *case* labels.

echo wordlist

The specified words are written to the shell's standard output. A `\c` causes the echo to complete without printing a newline. A `\n` in *wordlist* causes a newline to be printed. Otherwise the words are echoed, separated by spaces.

else

end

endif

endsw

See the description of the *foreach*, *if*, *switch*, and *while* statements below.

exec command

The specified command is executed in place of the current shell.

exit

exit(expr)

The shell exits either with the value of the *status* variable (first form) or with the value of the specified *expr* (second form).

foreach name (wordlist)

...

end

The variable *name* is successively set to each member of *wordlist* and the sequence of commands between this command and the matching *end* are executed. (Both *foreach* and *end* must appear alone on separate lines.)

The built-in command *continue* may be used to continue the loop prematurely and the built-in command *break* to terminate it prematurely. When this command is read from the terminal, the loop is read up once prompting with `?` before any statements in the loop are executed.

glob wordlist

Like *echo* but no `\` escapes are recognized and words are delimited by null characters in the output. Useful for programs which wish to use the shell to filename expand a list of words.

goto word

The specified *word* is filename and command expanded to yield a string of the form label. The shell rewinds its input as much as possible and searches for a line of the form label: possibly preceded by blanks or tabs. Execution continues after the specified line.

history

Displays the history event list.

if (expr) command

If the specified expression evaluates true, then the single *command* with arguments is executed. Variable substitution on *command* happens early, at the same time it does for the rest of the *if* command. *Command* must be a simple command, not a pipeline, a command list, or a parenthesized command list. Input/output redirection occurs even if *expr* is false, when command is **not** executed.

if (expr) then

...

else if (expr2) then

...

else

...

endif

If the specified *expr* is true then the commands to the first *else* are executed; else if *expr2* is true then the commands to the second *else* are executed, etc. Any number of *else-if* pairs are possible; only one *endif* is needed. The *else* part is likewise optional. (The words *else* and *endif* must appear at the beginning of input lines; the *if* must appear alone on its input line or after an *else*.)

logout

Terminates a login shell. The only way to log out if *ignoreeof* is set.

nice

nice +number

nice command

nice +number command

The first form sets the *nice* for this shell to 4. The second form sets the *nice* to the given number. The final two forms run command at priority 4 and *number* respectively. The super-user may specify negative niceness by using "nice -number" The command is always executed in a subshell, and the restrictions placed on commands in simple *if* statements apply.

nohup**nohup command**

The first form can be used in shell scripts to cause hangups to be ignored for the remainder of the script. The second form causes the specified command to be run with hangups ignored. Unless the shell is running detached, *nohup* has no effect. All processes detached with *&* are automatically *nohuped*. (Thus, *nohup* is not really needed.)

onintr**onintr -****onintr label**

Controls the action of the shell on interrupts. The first form restores the default action of the shell on interrupts which is to terminate shell scripts or to return to the terminal command input level. The second form *onintr -* causes all interrupts to be ignored. The final form causes the shell to execute a *goto* label when an interrupt is received or a child process terminates because it was interrupted.

In any case, if the shell is running detached and interrupts are being ignored, all forms of *onintr* have no meaning and interrupts continue to be ignored by the shell and all invoked commands.

rehash

Causes the internal hash table of the contents of the directories in the *path* variable to be recomputed. This is needed if new commands are added to directories in the *path* while you are logged in. This should only be necessary if you add commands to one of your own directories, or if a systems programmer changes the contents of one of the system directories.

repeat count command

The specified *command* which is subject to the same restrictions as the *command* in the one line *if* statement above, is executed *count* times. I/O redirection occurs exactly once, even if *count* is 0.

set**set name****set name=word****set name[index]=word****set name=(wordlist)**

The first form of the command shows the value of all shell variables. Variables which have other than a single word as value print as a parenthesized word list. The second form sets *name* to the null string. The third form sets *name* to the single *word*. The fourth form sets the *indexth* component of name to word; this component must already exist. The final form sets *name* to the list of words in *wordlist*. In all cases the

value is command and filename expanded.

These arguments may be repeated to set multiple values in a single set command. Note however, that variable expansion happens for all arguments before any setting occurs.

setenv name value

Sets the value of the environment variable *name* to be *value*, a single string. Useful environment variables are TERM, the type of your terminal and SHELL, the shell you are using.

shift

shift variable

The members of *argv* are shifted to the left, discarding *argv[1]*. It is an error for *argv* not to be set or to have less than one word as value. The second form performs the same function on the specified variable.

source name

The shell reads commands from *name*. *Source* commands may be nested; if they are nested too deeply, the shell may run out of file descriptors. An error in a *source* at any level terminates all nested *source* commands. Input during *source* commands is **never** placed on the history list.

switch (string)

case str1:

...

breaksw

...

default:

...

breaksw

endsw

Each case label is successively matched, against the specified *string* which is first command and filename expanded. The file metacharacters *, ?, and [...] may be used in the case labels, which are variable expanded. If none of the labels match before a default label is found, then the execution begins after the default label. Each case label and the default label must appear at the beginning of a line. The command *breaksw* causes execution to continue after the *endsw*. Otherwise control may fall through case labels and default labels, as in C. If no label matches and there is no default, execution continues after the *endsw*.

time

time command

With no argument, a summary of time used by this shell and its children is printed. If arguments are given, the specified simple command is timed and a time summary as described under the *time* variable is printed. If necessary, an extra shell

is created to print the time statistic when the command completes.

umask**umask value**

The file creation mask is displayed (first form) or set to the specified value (second form). The mask is given in octal. Common values for the mask are 002 giving all access to the group and read and execute access to others, or 022 giving all access except no write access for users in the group or others.

unalias pattern

All aliases whose names match the specified pattern are discarded. Thus, all aliases are removed by `unalias *`. It is not an error for nothing to be *unaliased*.

unhash

Use of the internal hash table to speed location of executed programs is disabled.

unset pattern

All variables whose names match the specified pattern are removed. Thus, all variables are removed by `unset *`; this has noticeably distasteful side-effects. It is not an error for nothing to be *unset*.

wait

All child processes are waited for. If the shell is interactive, then an interrupt can disrupt the wait, at which time the shell prints names and process numbers of all children known to be outstanding.

while (expr)

...

end

While the specified expression evaluates nonzero, the commands between the *while* and the matching *end* are evaluated. *Break* and *continue* may be used to terminate or continue the loop prematurely. (The *while* and *end* must appear alone on their input lines.) Prompting occurs here the first time through the loop as for the *foreach* statement if the input is a terminal.

@

@ name = expr

@ name[index] = expr

The first form prints the values of all the shell variables. The second form sets the specified *name* to the value of *expr*. If the expression contains `<`, `>`, `&` or `|` then at least this part of the expression must be placed within `()`. The third form assigns the value of *expr* to the *indexth* argument of *name*. Both *name* and its *indexth* component must already exist.

The operators `*=`, `+=`, etc. are available as in C. The space separating the name from the assignment operator is optional. Spaces are mandatory in separating components of *expr* which would otherwise be single words.

Special postfix `++` and `--` operators increment and decrement *name* respectively, i.e. `@ i++`.

Predefined Variables

The following variables have special meaning to the shell. Of these, *argv*, *child*, *home*, *path*, *prompt*, *shell* and *status* are always set by the shell. Except for *child* and *status* this setting occurs only at initialization; these variables will not be modified unless done explicitly by the user.

The shell copies the environment variable *PATH* into the variable *path*, and copies the value back into the environment whenever *path* is set. Thus it is not necessary to worry about its setting other than in the file *.cshrc* as inferior *csh* processes will import the definition of *path* from the environment.

argv	Set to the arguments to the shell, it is from this variable that positional parameters are substituted, i.e., <code>\$1</code> is replaced by <code>\$argv[1]</code> , etc.
cdpath	Gives a list of alternate directories searched to find subdirectories in <i>cd</i> commands.
child	The process number printed when the last command was forked with <code>&</code> . This variable is <i>unset</i> when this process terminates.
echo	Set when the <code>-x</code> command line option is given. Causes each command and its arguments to be echoed just before it is executed. For nonbuilt-in commands all expansions occur before echoing. Builtin commands are echoed before command and filename substitution, since these substitutions are then done selectively.
histchars	Can be assigned a two-character string. The first character is used as a history character in place of <code>!</code> , the second character is used in place of the <code>^</code> substitution mechanism. For example, set <code>histchars=";"</code> will cause the history characters to be comma and semicolon.
history	Can be given a numeric value to control the size of the history list. Any command which has been referenced in this many events will not be

discarded. A *history* that is too large may run the shell out of memory. The last executed command is always saved on the history list.

home	The home directory of the invoker, initialized from the environment. The filename expansion of <code>~</code> refers to this variable.
ignoreeof	If set, the shell ignores end-of-file from input devices that are terminals. This prevents a shell from accidentally being terminated by pressing Ctrl-D.
mail	<p>The files where the shell checks for mail. This is done after each command completion which will result in a prompt, if a specified interval has elapsed. The shell responds with, "You have new mail" if the file exists with an access time not greater than its modify time.</p> <p>If the first word of the value of <i>mail</i> is numeric, it specifies a different mail checking interval: in seconds, rather than the default, which is 10 minutes.</p> <p>If multiple mail files are specified, then the shell responds with "New mail in <i>name</i>", when there is mail in the file <i>name</i>.</p>
noclobber	As described in the section <i>Input/Output</i> , restrictions are placed on output redirection to insure that files are not accidentally destroyed, and that <code>>></code> redirections refer to existing files.
noglob	If set, filename expansion is inhibited. This is most useful in shell scripts which are not dealing with filenames, or after a list of filenames has been obtained and further expansions are not desirable.
nonomatch	If set, it is not an error for a filename expansion to not match any existing files; rather, the primitive pattern is returned. It is still an error for the primitive pattern to be malformed, i.e., <code>echo [</code> still gives an error.
path	Each word of the path variable specifies a directory in which commands are to be sought for execution. A null word specifies the current directory. If there is no <i>path</i> variable, then only full pathnames will execute. The usual search path is <code>/bin</code> , <code>/usr/bin</code> , and <code>.</code> , but this may vary from system to system. For the super-user, the default search path is <code>/etc</code> , <code>/bin</code> and <code>/usr/bin</code> . A shell which is

given neither the **-c** nor the **-t** option will normally hash the contents of the directories in the *path* variable after reading *.cshrc*, and each time the *path* variable is reset. If new commands are added to these directories while the shell is active, it may be necessary to give the *rehash* command, or the commands may not be found.

prompt	The string which is printed before each command is read from an interactive terminal input. If a ! appears in the string, it will be replaced by the current event number unless a preceding \ is given. Default is % , or # for the super-user.
shell	The file in which the shell resides. This is used in forking shells to interpret files which have execute bits set, but which are not executable by the system. (See the description of <i>Nonbuilt-In Command Execution</i> below.) Initialized to the (system-dependent) home of the shell.
status	The status returned by the last command. If it terminated abnormally, then 0200 is added to the status. Built-in commands which fail return exit status 1, all other built-in commands set status 0.
time	Controls automatic timing of commands. If set, then any command which takes more than this many cpu seconds will cause a line giving user, system, real time, and a utilization percentage which is the ratio of user plus system times to real time to be printed when it terminates.
verbose	Set by the -v command line option, causes the words of each command to be printed after history substitution.

Nonbuilt-In Command Execution

When a command to be executed is found to not be a built-in command, the shell attempts to execute the command via *exec(S)*. Each word in the variable *path* names a directory from which the shell will attempt to execute the command. If it is given neither a **-c** nor a **-t** option, the shell will hash the names in these directories into an internal table so that it will only try an *exec* in a directory if there is a possibility that the command resides there. This greatly speeds command location when a large number of directories are present in the search path. If this mechanism has been turned off (via *unhash*), or if the shell was given a **-c** or **-t** argument, and in any case for each directory component of *path* which does not begin with a **/**, the shell concatenates with the given command

name to form a pathname of a file which it then attempts to execute.

Parenthesized commands are always executed in a subshell. Thus `(cd ; pwd) ; pwd` prints the *home* directory; leaving you where you were (printing this after the home directory), while `cd ; pwd` leaves you in the home directory. Parenthesized commands are most often used to prevent *cd* from affecting the current shell.

If the file has execute permissions but is not an executable binary to the system, then it is assumed to be a file containing shell commands and a new shell is spawned to read it.

If there is an *alias* for *shell* then the words of the alias are prepended to the argument list to form the shell command. The first word of the *alias* should be the full pathname of the shell (e.g. `$shell`). Note that this is a special, late occurring, case of *alias* substitution, and only allows words to be prepended to the argument list without modification.

Argument List Processing

If argument 0 to the shell is `-` then this is a login shell. The flag arguments are interpreted as follows:

- c Commands are read from the (single) following argument which must be present. Any remaining arguments are placed in *argv*.
- e The shell exits if any invoked command terminates abnormally or yields a nonzero exit status.
- f The shell will start faster, because it will neither search for nor execute commands from the file `.cshrc` in the invoker's home directory.
- i The shell is interactive and prompts for its top-level input, even if it appears to not be a terminal. Shells are interactive without this option if their input and output are terminals.
- n Commands are parsed, but not executed. This may aid in syntactic checking of shell scripts.
- s Command input is taken from the standard input.
- t A single line of input is read and executed. A `\` may be used to escape the newline at the end of this line and continue onto another line.
- v Causes the *verbose* variable to be set, with the effect that command input is echoed after history substitution.

- x Causes the *echo* variable to be set, so that commands are echoed immediately before execution.
- V Causes the *verbose* variable to be set even before *.cshrc* is executed.
- X Causes the *echo* variable to be set even before *.cshrc* is executed.

After processing of flag arguments, if arguments remain but none of the *-c*, *-i*, *-s*, or *-t* options were given, the first argument is taken as the name of a file of commands to be executed. The shell opens this file, and saves its name for possible resubstitution by *\$0*. On a typical system, most shell scripts are written for the standard shell (see *sh(C)*), the C shell will execute such a standard shell if the first character of a script is not a *#* (i.e. if the script does not start with a comment). Remaining arguments initialize the variable *argv*.

Signal Handling

The shell normally ignores *quit* signals. The *interrupt* and *quit* signals are ignored for an invoked command if the command is followed by *&*; otherwise the signals have the values which the shell inherited from its parent. The shells handling of interrupts can be controlled by *onintr*. Login shells catch the *terminate* signal; otherwise this signal is passed on to children from the state in the shell's parent. In no case are interrupts allowed when a login shell is reading the file *.logout*.

Files

<i>~/.cshrc</i>	Read at by each shell at the beginning of execution
<i>/etc/cshrc</i>	Systemwide default <i>cshrc</i> file if none is present
<i>~/.login</i>	Read by login shell, after <i>.cshrc</i> at login
<i>~/.logout</i>	Read by login shell, at logout
<i>/bin/sh</i>	Shell for scripts not starting with a <i>#</i>
<i>/tmp/sh*</i>	Temporary file for <i><<</i>
<i>/dev/null</i>	Source of empty file
<i>/etc/passwd</i>	Source of home directories for <i>~name</i>

Limitations

Words can be no longer than 512 characters. The number of arguments to a command which involves filename expansion is limited to 1/6 number of characters allowed in an argument list, which is 5120, less the characters in the environment. Also, command substitutions may substitute no more characters than are allowed in an argument list.

To detect looping, the shell restricts the number of *alias* substitutions on a single line to 20.

Credit

This utility was developed at the University of California at Berkeley and is used with permission.

Notes

Built-in control structure commands like **foreach** and **while** cannot be used with `|` & or `;`.

Commands within loops, prompted for by `?`, are not placed in the *history* list.

It is not possible to use the colon (`:`) modifiers on the output of command substitutions.

*cs**h* attempts to import and export the PATH variable for use with regular shell scripts. This only works for simple cases, where the PATH contains no command characters.

This version of *cs**h* does not support or use the process control features of the 4th Berkeley Distribution.

Name

csplit – Splits files according to context.

Syntax

csplit [**-s**] [**-k**] [**-f** *prefix*] *file* *arg1* [. . . *argn*]

Description

csplit reads *file* and separates it into *n*+1 sections, defined by the arguments *arg1* . . . *argn*. By default the sections are placed in *xx00* . . . *xxn* (*n* may not be greater than 99). These sections get the following pieces of *file*:

- 00: From the start of *file* up to (but not including) the line referenced by *arg1*.
- 01: From the line referenced by *arg1* up to the line referenced by *arg2*.
- ⋮
- n*+1: From the line referenced by *argn* to the end of *file*.

The options to *csplit* are:

- s** *csplit* normally prints the character counts for each file created. If the **-s** option is present, *csplit* suppresses the printing of all character counts.
- k** *csplit* normally removes created files if an error occurs. If the **-k** option is present, *csplit* leaves previously created files intact.
- f** *prefix* If the **-f** option is used, the created files are named *prefix00* . . . *prefixn*. The default is *xx00* . . . *xxn*.

The arguments (*arg1* . . . *argn*) to *csplit* can be a combination of the following:

/rexp/ A file is to be created for the section from the current line up to (but not including) the line containing the regular expression *rexp*. The current line becomes the line containing *rexp*. This argument may be followed by an optional **+** or **-** some number of lines (e.g., */Page/-5*).

%rexp% This argument is the same as */rexp/*, except that no file is created for the section.

- lnno* A file is to be created from the current line up to (but not including) *lnno*. The current line becomes *lnno*.
- {*num*} Repeat argument. This argument may follow any of the above arguments. If it follows a *rexp* type argument, that argument is applied *num* more times. If it follows *lnno*, the file will be split every *lnno* lines (*num* times) from that point.

Enclose all *rexp* type arguments that contain blanks or other characters meaningful to the shell in the appropriate quotation marks. Regular expressions may not contain embedded newlines. *csplit* does not affect the original file; it is the users responsibility to remove it.

Examples

```
csplit -f cobol file '/procedure division/' /par5./ /par16./
```

This example creates four files, **cobol00** . . . **cobol03**. After editing the "split" files, they can be recombined as follows:

```
cat cobol0[0-3] > file
```

Note that this example overwrites the original file.

```
csplit -k file 100 {99}
```

This example would split the file at every 100 lines, up to 10,000 lines. The **-k** option causes the created files to be retained if there are less than 10,000 lines; however, an error message would still be printed.

```
csplit -k prog.c '%main(%' '^')/ +1' {20}
```

Assuming that **prog.c** follows the normal C coding convention of ending routines with a **}** at the beginning of the line, this example will create a file containing each separate C routine (up to 21) in **prog.c**.

ed(C), sh(C), regex(S)

Diagnostics

Self-explanatory except for:

arg – out of range

which means that the given argument did not reference a line between the current position and the end of the file.

Name

cu - Calls another XENIX system.

Syntax

cu [-*sspeed*] [-*aacu*] [-*lline*] [-*h*] [-*o*|-*e*] *telno*

cu [-*sspeed*] [-*lline*] [-*h*] [-*o*|-*e*] *dir*

Description

cu "calls up" another XENIX system through a modem or a direct serial connection. It also controls the transmission and reception of data and programs during the call. *cu* looks at each line in the file */usr/lib/uucp/L-devices* until it finds a line that matches the options given in the command line. If it finds an appropriate line, it will attempt to make a connection. If it cannot find the proper line, *cu* quits.

The options are:

-*sspeed*

Specifies the transmission speed. 1200 baud is the default value. Other speeds available are 110, 150, 300, 1200, 2400, 4800 and 9600 baud. Directly connected lines may be set to other speeds. Most modems are restricted to 300 and 1200 baud.

-*aacu*

Specifies the device name of the ACU (automatic calling unit) device. If not specified, *cu* will use the first available *acu* with the right speed.

-*lline*

Specifies the device name of the communications line. If not specified, *cu* will use the first available direct line (if *dir* is specified) or *acu* (if a *telno* is specified) with the right speed.

-*h*

Emulates local echo. This feature supports calls to systems that expect half-duplex mode terminals.

-*e*

Specifies that even-parity data is to be generated for data sent to the remote system.

-*o*

Specifies that odd-parity data is to be generated for data sent to the remote system.

Telno is the telephone number of the remote system.

For *acu* connections, *cu* invokes `/usr/lib/uucp/dial` to dial the modem. Consult your modem manual to determine the correct sequences to include in the phone number for pauses, pulse dialing, etc.

For directly connected lines, the string "dir" is used instead of *telno*. See the Examples later in this section for sample command lines.

After making the connection, *cu* runs as two processes: *transmit* and *receive*. The *transmit* process reads data from the standard input and, except for lines beginning with a tilde (~), passes it to the remote system. The *receive* process accepts data from the remote system and, except for lines beginning with a tilde, passes it to the standard output. Normally, an automatic XON/XOFF (DC3/DC1) protocol controls input from the remote system so the buffer is not overrun. Lines beginning with a tilde have special meanings.

The *transmit* process interprets lines beginning with a tilde as follows:

- ~. Terminates the conversation.
- ~! Escapes to an interactive shell on the local system.
- ~!cmd... Runs *cmd* on the local system (via `sh -c`).
- ~\$cmd... Runs *cmd* locally and sends its output to the remote system.
- ~%take *remote* [*local*]
Copies file *remote* (on the remote system) to file *local* on the local system. If *local* is omitted, the *remote* filename is used in both places. Use of this line requires the existence of *echo*(C) and *cat*(C) on the remote system. If tabs are to be copied without expansion, `stty tabs` mode should be set on the remote system.
- ~%put *local* [*remote*]
Copies file *local* (on the local system) to file *remote* on the remote system. If *local* is omitted, the *remote* filename is used in both places. Use of this line requires the existence of *stty*(C) and *cat*(C) on the remote system. It also requires that the current erase and kill characters on the remote system be identical

to the current ones on the local system. Backslashes are inserted at appropriate places.

<code>~%b</code> or <code>~%break</code>	Sends a break char to the remote system.
<code>~...</code>	Sends the line <code>~...</code> to the remote system.
<code>~%nostop</code>	Turns off the XON/XOFF input control protocol for the remainder of the session. This is useful if the remote system is one which does not respond properly to the XON/XOFF characters.

The *receive* process normally copies data from the remote system to its standard output. A line from the remote system that begins with `~>` diverts the output to a file. Data is appended to a file if `~>>` is used. The diversion is terminated by a trailing `~>`. The complete sequence is:

```
~> [>]: file
zero or more lines to be written to file
~>
```

Examples

A sample command for a dialup connection is:

```
cu 5559801
```

cu selects the first available *acu* at the default speed of 1200 baud.

A sample command for a direct connection is:

```
cu dir
```

cu will select the first available direct line at the default speed of 1200 baud.

You can force *cu* to use a specific *acu* device, *line* device or *speed* with the command line options `-a`, `-l` and `-s`. This is useful if you wish to use the same modem for dialup connections at both 300 and 1200 baud, or if you have more than one directly connected computer. For example:

```
cu -a tty12 -s 300 5559801
```

will force *cu* to place the call through `/dev/tty12` at 300 baud.

```
cu -l tty12 dir
```

will cause **/dev/tty12** to be used for a direct connection at 1200 baud.

Files

/usr/lib/uucp/L-devices

Device information

/usr/lib/uucp/dial

Dialer program

See Also

cat(C), echo(C), stty(C), tty(M)

Diagnostics

Exit code is zero for normal exit, nonzero (various values) otherwise.

Device busy: Someone else is using the desired line.

Notes

There is an artificial slowing of transmission by *cu* during the `~%put` operation so that loss of data is unlikely.

ASCII files only can be transferred using `~%take` or `~%put`; binary files cannot be transferred.

cu opens devices for exclusive use. If *cu* terminates abnormally, the device may remain locked.

Name

custom - Installs specific portions of the XENIX System

Syntax

custom [-odt] [-irl [package]] [-f [file]]

Description

With *custom* you can create a custom installation by selectively installing or deleting portions of the XENIX system. *custom* is executable only by the super-user and is either interactive or can be invoked from the command line with several options.

Files are extracted or deleted in *packages*. A package is a collection of individual files. Packages are grouped together in *sets*.

Three default *sets* are always available:

- Operating System
- Development System
- Text Processing System

You can also install additional *sets*. You can list the available *packages* by using the *custom* command as described next.

Usage

To use *custom* interactively, enter:

custom

You see a list of sets. For example:

1. Operating System
2. Development System
3. Text Processing System
4. Add a Supported Product

The program prompts you to choose a set from which to work. If the data files for that set are not already installed on the hard disk, *custom* prompts you for the floppy which contains these data files and installs them. You may also see menu items for each product that has been previously added using the "Add a Supported Product" option. If you are adding a new product, you will be prompted for volume 1 of the new procust distribution and *custom* will extract the product information necessary to support it.

When you select a valid set, you see a menu like this:

1. Install one or more packages
2. Remove one or more packages
3. List the files in a package
4. Install a single file
5. Select a new set to customize
6. Display current disk usage
7. Help

When you enter a menu option, you are prompted for further information. This is what the options prompt, and what action occurs:

1. Install

Prompts for one or more package names.

Calculates which installation volumes (distribution media) are needed, then prompts for the correct volume numbers. If multiple packages are specified, the names should be separated by spaces on the command line.

This option, as well as "2" and "3," displays a list of all available packages in the currently selected set. Each line describes the package name, whether the package is fully installed, not installed or partially installed, the size of the package (in 512 byte blocks), and a one line description of the package contents.

2. Remove

Prompts for one or more package names.

Deletes the correct files in the specified package. If multiple packages are specified the names should be separated by spaces on the command line.

Displays available packages (see option "1").

3. List files in a package

Lists all files in the specified package.

Prompts for one or more package names. Enter the name of the desired package(s).

Displays available packages (see option "1").

4. Install a single file
Extract the specified file from the distribution set.

Filename should be a full pathname relative to the root directory
“/”.
5. Select a new set

Allows you to work from a different set than the current one.
6. Display current disk usage

Tells you your current disk usage.
7. Help

Prints a page of instructions to help you use *custom*.

Options

Three arguments are required for a completely non-interactive use of *custom*:

A set identifier
(-o, -d, or -t),

A command
(-i, -r, -l,
or
-f),

And either one or more package names, or a file name

If any information is missing from the command line, *custom* prompts for the missing data.

Only one of -o, -d, or -t may be specified. These stand for:

-o
Operating System
-d
Development System
-t
Text Processing System

Only one of -i, -r, -l, or -f may be specified, followed by an argument of the appropriate type (one or more package names, or a file name). These options perform the following:

- i Install the specified package(s)
- r Remove the specified package(s)
- l List the files in the specified package(s).
- f Install the specified file.

Files

/etc/base.perms
/etc/soft.perms
/etc/text.perms
/etc/perms/*

See Also

fixperm(M), df(C), du(C), install(C)

Notes

If you upgrade any part of your system, *custom* detects if you have a different release and prompts you to insert the floppy volume that updates the custom data files. Likewise, if you insert an invalid product or a volume out of order, you will be prompted to reinsert the correct volume.

Name

`date` – Prints and sets the date.

Syntax

`date [mmddhhmm[yy]] [+format]`

Description

If no argument is given, or if the argument begins with `+`, the current date and time are printed. Otherwise, the current date is set. The first *mm* is the month number; *dd* is the day number in the month; *hh* is the hour number (24-hour system); the second *mm* is the minute number; *yy* is the last 2 digits of the year number and is optional. For example:

`date 10080045`

sets the date to Oct 8, 12:45 AM. The current year is the default if no year is mentioned. The system operates in GMT. *date* takes care of the conversion to and from local standard and daylight time.

If the argument begins with `+`, the output of *date* is under the control of the user. The format for the output is similar to that of the first argument to *printf* (S). All output fields are of fixed size (zero padded if necessary). Each field descriptor is preceded by a percent sign (%) and will be replaced in the output by its corresponding value. A single percent sign is encoded by doubling the percent sign, i.e., by specifying “%%”. All other characters are copied to the output without change. The string is always terminated with a newline character.

Field Descriptors:

- n** Inserts a newline character
- t** Inserts a tab character
- m** Month of year – 01 to 12
- d** Day of month – 01 to 31
- y** Last 2 digits of year – 00 to 99
- D** Date as mm/dd/yy

H Hour – 00 to 23
M Minute – 00 to 59
S Second – 00 to 59
T Time as HH:MM:SS
j Julian date – 001 to 366
w Day of the week – Sunday = 0
a Abbreviated weekday – Sun to Sat
h Abbreviated month – Jan to Dec
r Time in AM/PM notation

Example

The line

```
date '+DATE: %m/%d/%y%nTIME: %H:%M:%S'
```

generates as output:

```
DATE: 08/01/76  
TIME: 14:45:05
```

Diagnostics

<i>no permission</i>	You aren't the super-user and you are trying to change the date.
<i>bad conversion</i>	The date set is syntactically incorrect.
<i>bad format character</i>	The field descriptor is not recognizable.

Name

dc - Invokes an arbitrary precision calculator.

Syntax

dc [file]

Description

dc is an arbitrary precision arithmetic package. Ordinarily it operates on decimal integers, but you may specify an input base, output base, and a number of fractional digits to be maintained. The overall structure of *dc* is a stacking (reverse Polish) calculator. If an argument is given, input is taken from that file until its end, then from the standard input. The following constructions are recognized:

number

The value of the number is pushed on the stack. A number is an unbroken string of the digits 0-9. It may be preceded by an underscore (*_*) to input a negative number. Numbers may contain decimal points.

+ - / * % ^

The top two values on the stack are added (*+*), subtracted (*-*), multiplied (***), divided (*/*), remaindered (*%*), or exponentiated (*^*). The two entries are popped off the stack; the result is pushed on the stack in their place. Any fractional part of an exponent is ignored.

sx The top of the stack is popped and stored into a register named *x*, where *x* may be any character. If the *s* is capitalized, *x* is treated as a stack and the value is pushed on it.

lx The value in register *x* is pushed on the stack. The register *x* is not altered. All registers start with zero value. If the *l* is capitalized, register *x* is treated as a stack and its top value is popped onto the main stack.

d The top value on the stack is duplicated.

p The top value on the stack is printed. The top value remains unchanged. *p* interprets the top of the stack as an ASCII string, removes it, and prints it.

f All values on the stack are printed.

- q** Exits the program. If executing a string, the recursion level is popped by two. If **q** is capitalized, the top value on the stack is popped and the string execution level is popped by that value.
- x** Treats the top element of the stack as a character string and executes it as a string of *dc* commands.
- X** Replaces the number on the top of the stack with its scale factor.
- [...]** Puts the bracketed ASCII string onto the top of the stack.
- <x >x =x**
The top two elements of the stack are popped and compared. Register *x* is evaluated if they obey the stated relation.
- v** Replaces the top element on the stack by its square root. Any existing fractional part of the argument is taken into account, but otherwise the scale factor is ignored.
- !** Interprets the rest of the line as a XENIX command.
- c** All values on the stack are popped.
- i** The top value on the stack is popped and used as the number radix for further input.
- I** Pushes the input base on the top of the stack.
- o** The top value on the stack is popped and used as the number radix for further output.
- O** Pushes the output base on the top of the stack.
- k** The top of the stack is popped, and that value is used as a nonnegative scale factor; the appropriate number of places are printed on output, and maintained during multiplication, division, and exponentiation. The interaction of scale factor, input base, and output base will be reasonable if all are changed together.
- z** The stack level is pushed onto the stack.
- Z** Replaces the number on the top of the stack with its length.
- ?** A line of input is taken from the input source (usually the terminal) and executed.

; : Used by *bc* for array operations.

Example

This example prints the first ten values of $n!$:

```
[1a1+dsa*pla10>y]sy
0sa1
lyx
```

See Also

bc(C)

Diagnostics

<i>x is unimplemented</i>	The octal number <i>x</i> corresponds to a character that is not implemented as a command
<i>stack empty</i>	Not enough elements on the stack to do what was asked
<i>Out of space</i>	The free list is exhausted (too many digits)
<i>Out of headers</i>	Too many numbers being kept around
<i>Out of pushdown</i>	Too many items on the stack
<i>Nesting Depth</i>	Too many levels of nested execution

Notes

bc is a preprocessor for *dc*, providing infix notation and a C-like syntax which implements functions and reasonable control structures for programs. For interactive use, *bc* is preferred to *dc*.

Name

dd – Converts and copies a file.

Syntax

dd [option=value] ...

Description

dd copies the specified input file to the specified output with possible conversions. The standard input and output are used by default. The input and output block size may be specified to take advantage of raw physical I/O.

<i>Option</i>	<i>Value</i>
if=file	Input filename; standard input is default
of=file	Output filename; standard output is default
ibs=n	Input block size <i>n</i> bytes (default is BSIZE block size)
obs=n	Output block size (default is BSIZE block size)
bs=n	Sets both input and output block size, superseding <i>ibs</i> and <i>obs</i> ; also, if no conversion is specified, it is particularly efficient since no in-core copy needs to be done
cbs=n	Conversion buffer size
skip=n	Skips <i>n</i> input records before starting copy
seek=n	Seeks <i>n</i> records from beginning of output file before copying
count=n	Copies only <i>n</i> input records
conv=ascii	Converts EBCDIC to ASCII
conv=ebcdic	Converts ASCII to EBCDIC
conv=ibm	Slightly different map of ASCII to EBCDIC
conv=lcase	Maps alphabetics to lowercase <i>Option Value</i>

conv=ucase Maps alphabetic to uppercase

conv=swab Swaps every pair of bytes

conv=sync Pads every input record to *ibs*

conv="... , ..." Several comma-separated conversions

Where sizes are specified, a number of bytes is expected. A number may end with *k*, *b*, or *w* to specify multiplication by 1024, 512, or 2 respectively; a pair of numbers may be separated by *x* to indicate a product.

Cbs is used only if *ascii* or *ebcdic* conversion is specified. In the former case *cbs* characters are placed into the conversion buffer, converted to ASCII, and trailing blanks trimmed and newline added before sending the line to the output. In the latter case ASCII characters are read into the conversion buffer, converted to EBCDIC, and blanks added to make up an output record of size *cbs*.

After completion, *dd* reports the number of whole and partial input and output blocks.

Examples

This command reads an EBCDIC tape, blocked ten 80-byte EBCDIC card images per record, into the ASCII file **outfile** :

```
dd if=/dev/rmt0 of=outfile ibs=800 cbs=80 conv=ascii,lcase
```

Note the use of raw magtape. *dd* is especially suited to I/O on raw physical devices because it allows reading and writing in arbitrary record sizes.

See Also

copy(C), cp(C), tar(C)

Diagnostics

f+p records in(out) Numbers of full and partial records read(written)

Notes

The ASCII/EBCDIC conversion tables are taken from the 256-character standard in the CACM Nov, 1968. The *ibm* conversion corresponds better to certain IBM print train conventions. There is no universal solution.

Newlines are inserted only on conversion to ASCII; padding is done only on conversion to EBCDIC.

Name

devnm – Identifies device name.

Syntax

/etc/devnm [names]

Description

Devnm identifies the special file associated with the mounted file system where the argument *name* resides.

This command is most commonly used by **/etc/rc** to construct a mount table entry for the **root** device.

Examples

Be sure to type full pathnames in this example:

/etc/devnm /usr

If **/dev/hd1** is mounted on **/usr**, this produces:

hd1 /usr

Files

/dev/* Device names

/etc/rc Xenix startup commands

See Also

setmnt(C)

Name

df – Report number of free disk blocks.

Syntax

```
df [ -t ] [ -f ] [ -v -i ] [ file-systems ]
```

Description

df prints out the number of free blocks and free inodes available for on-line file systems by examining the counts kept in the super-blocks; *file-systems* may be specified by device name (e.g., */dev/root*). If the *file-systems* argument is unspecified, the free space on all of the mounted file systems is sent to the standard output. The list of mounted file systems is given in */etc/mnttab*.

Options include:

- t** Causes total allocated block figures to be reported as well as number of free blocks.
- f** Reports only an actual count of the blocks in the free list (free inodes are not reported). With this option, *df* reports on raw devices.
- v** Reports the percent of blocks used as well as the number of blocks used and free.
- i** Reports the percent of inodes used as well as the number of inodes used and free. Use the **-i** option with the **-v** option to display counts of blocks and inodes free as well as the percentage of inodes and blocks used.

The **-v** and **-i** options can not be used with other *df* options.

Files

*/dev/**
/etc/mnttab

See Also

fsck(C), mount(C), mnttab(F)

Notes

See *Notes* under *mount*(C).

This utility reports sizes in 512 byte blocks. On systems which use 1024 byte blocks, this means a file of 500 bytes uses 2 blocks. *df* will report 2 blocks less free space, rather than 1 block, since the file uses one system block of 1024 bytes. Refer to the **machine**(HW) manual page for the block size used by your system.

Name

`diff` - Compares two text files.

Syntax

`diff [-efbh] file1 file2`

Description

`diff` tells what lines must be changed in two files to bring them into agreement. If *file1* or *file2* is a dash (-), the standard input is used. If *file1* or *file2* is a directory, `diff` uses the file in that directory that has the same name as file (*file2* or *file1* respectively) it is compared to. For example:

```
diff /tmp dog
```

compares the file named *dog*, that is in the */tmp* directory, with the file *dog* in the current directory. The normal output contains lines of these forms:

```
n1 a n3,n4
n1,n2 d n3
n1,n2 c n3,n4
```

These lines resemble *ed* commands to convert *file1* into *file2*. The numbers after the letters pertain to *file2*. In fact, by exchanging a for d and reading backward, one may ascertain equally how to convert *file2* into *file1*. As in *ed*, identical pairs where *n1* = *n2* or *n3* = *n4* are abbreviated as a single number.

Following each of these lines come all the lines that are affected in the first file flagged by <, then all the lines that are affected in the second file flagged by >.

The **-b** option causes trailing blanks (spaces and tabs) to be ignored and other strings of blanks to compare equal.

The **-e** option produces a script of *a*, *c* and *d* commands for the editor *ed*, which will recreate *file2* from *file1*. The **-f** option produces a similar script, not useful with *ed*, in the opposite order. In connection with **-e**, the following shell procedure helps maintain multiple versions of a file:

```
(shift; cat $*; echo '1,$p') | ed - $1
```

This works by performing a set of editing operations on an original ancestral file. This is done by combining the sequence of *ed* scripts given as all command line arguments except the first. These scripts

are presumed to have been created with *diff* in the order given on the command line. The set of editing operations is then piped as an editing script to *ed* where all editing operations are performed on the ancestral file given as the first argument on the command line. The final version of the file is then printed on the standard output. Only an ancestral file (\$1) and a chain of version-to-version *ed* scripts (\$2,\$3,...) made by *diff* need be on hand.

Except in rare circumstances, *diff* finds the smallest sufficient set of file differences.

The **-h** option does a fast, less-rigorous job. It works only when changed stretches are short and well separated, but also works on files of unlimited length. The **-e** and **-f** cannot be used with the **-h** option.

Files

/tmp/d????

/usr/lib/diffh for **-h**

See Also

cmp(C), comm(C), ed(C)

Diagnostics

Exit status is 0 for no differences, 1 for some differences, 2 for errors.

Notes

Editing scripts produced under the **-e** or **-f** option do not always work correctly on lines consisting of a single period (.).

Name

diff3 – Compares three files.

Syntax

diff3 [**-ex3**] file1 file2 file3

Description

diff3 compares three versions of a file, and publishes disagreeing ranges of text flagged with these codes:

```
====          All three files differ
====1        File1 is different
====2        File2 is different
====3        File3 is different
```

The type of change suffered in converting a given range of a given file to some other range is indicated in one of these ways:

```
f : n1 a      Text is to be appended after line number n1 in
               file f, where f = 1, 2, or 3.

f : n1 , n2 c  Text is to be changed in the range line n1 to
               line n2. If n1 = n2, the range may be abbrevi-
               ated to n1.
```

The original contents of the range follows immediately after a **c** indication. When the contents of two files are identical, the contents of the lower-numbered file is suppressed.

Under the **-e** option, *diff3* publishes a script for the editor *ed* that will incorporate into *file1* all changes between *file2* and *file3*, i.e., the changes that normally would be flagged **====** and **====3**. The **-x** option produces a script to incorporate changes flagged with **====**. Similarly, the **-3** option produces a script to incorporate changes flagged with **====3**. The following command applies a resulting editing script to *file1*:

```
(cat script; echo '1,$p') | ed - file1
```

Files

/tmp/d3*

/usr/lib/diff3prog

See Also

diff(C)

Notes

The **-e** option does not work properly for lines consisting of a single period.

The input file size limit is 64K bytes.

Name

dircmp - Compares directories.

Syntax

dircmp [**-d**] [**-s**] [**-wn**] dir1 dir2

Description

dircmp examines *dir1* and *dir2* and generates tabulated information about the contents of the directories. Listings of files that are unique to each directory are generated in addition to a list that indicates whether the files common to both directories have the same contents.

There are three options available:

- d** Performs a full *diff* on each pair of like-named files if the contents of the files are not identical.
- s** Reports whether the files are "same" or "different".
- wn** Changes the width of the output line to *n* characters. The default width is 72.

See Also

cmp(C), diff(C).

Name

`dirname` – Delivers directory part of `pathname`.

Syntax

`dirname string`

Description

dirname delivers all but the last component of the *pathname* in *string* and prints the result on the standard output. If there is only one component in the *pathname*, only a “dot” is printed. It is normally used inside substitution marks (`` ``) within shell procedures.

The companion command *basename* deletes any prefix ending in a slash (`/`) and the *suffix* (if present in *string*) from *string*, and prints the result on the standard output.

Examples

The following example sets the shell variable `NAME` to `/usr/src/cmd`:

```
NAME=`dirname /usr/src/cmd/cat.c`
```

This example prints `/a/b/c` on the standard output:

```
dirname /a/b/c/d
```

This example prints a “dot” on the standard output:

```
dirname file.ext
```

See Also

`basename(C)`, `sh(C)`

Name

disable – Turns off terminals and printers.

Syntax

```
disable tty ...  
disable [-c][-r[reason]] printers
```

Description

For terminals, this program manipulates the */etc/ttys* file and signals *init* to disallow logins on a particular terminal. For printers, *disable* stops print requests from being sent to the named printer. The following options can be used:

- c** Cancels any requests that are currently printing.
- r[reason]** Associates a *reason* with disabling the printer. The *reason* applies to all printers listed up to the next **-r** option. If the **-r** option is not present or the **-r** option is given without a *reason*, then a default *reason* is used. *Reason* is reported by *lpstat*(C).

Examples

In this example, a printer named *linepr* is disabled because of a paper jam:

```
disable -r"paper jam" linepr
```

Files

```
/dev/tty*  
/etc/ttys  
/usr/spool/lp/*
```

See Also

login(M), enable(C), ttys(M), getty(M), init(M), lp(C), lpinit(C), lpstat(C)

Warning

Be absolutely certain to pause at least **one minute** before reusing this command or before using the *enable* command. Failure to do so may cause the system to crash.

Name

diskcp, diskcmp – Copies or compares floppy disks.

Syntax

```
diskcp [ -f ] [ -d ]  
diskcmp [ -d ]
```

Description

This command provides easy copying of a source floppy disk. **dd** is used to make an image of the source floppy (the one you wish to copy). On machines with one floppy drive **diskcp** temporarily transfers the image to the hard disk until a blank “target” floppy is inserted into the floppy drive. On machines with two floppy drives **dd** immediately places the image of the source floppy directly on the target floppy.

The options are:

- f Format the target floppy disk before the image is copied.
- d The computer has dual floppy drives. **diskcp** copies the image directly onto the target floppy.

diskcmp functions similarly to **diskcp**. It compares the contents of one floppy disk with the contents of a second floppy disk using the **cmp** utility. The syntax is the same as that of **diskcp**.

Examples

To make a copy of a floppy, place the source floppy in the drive and type:

```
diskcp
```

When **diskcp** is finished copying to the hard disk, it prompts you to insert the target floppy in the drive. If you specify the -f flag, **diskcp** will format the disk. When the copy is finished, **diskcp** asks if you would like to make another copy of the same source disk. When you answer ‘n’ it asks if you would like to copy another source disk.

Specify the -d flag on the command line if you have two floppy drives.

```
diskcp -d
```

Notes

If *diskcp* encounters a write error while copying the source image to the target disk, it will format the disk and try again. This happens most often when an unformatted floppy is used and the **-f** flag is not specified.

diskcp reads and writes to 48 tpi, double sided, 9 sector per track floppies (*/dev/fd048ds9*). The *diskcp* shell script can be edited to support other types of backup media.

Files

/usr/bin/diskcp
/usr/bin/diskcmp
/tmp/disk\$\$

See Also

dd(C), *cmp*(C)

Name

divvy - Disk dividing utility

Syntax

```
divvy -b block_device -c character_device [-v virtual_drive]
      [-p physical-drive] [-i [proto]]
```

Description

divvy divides a disk or *fdisk*(C) partition into a number of separate areas, also known as “devices” or “divisions.” A division is identified by unique major and minor device numbers and can be used for file systems, swap areas, and isolating bad spots on the disk.

With *divvy* you can:

- Divide a disk or *fdisk* partition into separate devices.
- Create new file systems.
- Change the device names of file systems.
- Change the size of file systems.
- Remove file systems.

Options

Options to *divvy* are:

- b *block_device*
Major device number of block interface.
- c *character_device*
Major device number of character interface.
- v *virtual_device*
For dividing a virtual drive.
- p *physical_drive*
For dividing one of several physical disks that share the same controller.
- i [proto]
Disk being divided will contain a **root** file system.

Usage

During XENIX installation, *divvy* prompts for the size of the swap area. Pressing RETURN selects a calculated "default" value. If the disk is large enough, *divvy* prompts for a separate /u (user) file system.

divvy may also prompt for block by block control over the layout of the file system or file systems. With block by block control, you can use *divvy* interactively to choose the exact layout of a particular disk or file system.

The device being divided must be a block device with a character interface. For example, to use *divvy* on a device with a block interface major number 1 and character interface number of 1, enter:

```
divvy -b 1 -c 1
```

The **-v** option specifies which virtual drive to divide. The default is the active drive. Here, "virtual drive" is the same as an MS-DOS partition. Virtual drive numbers are determined with the *fdisk*(C) utility.

The **-p** option allows division of one of several physical disks sharing a controller. *divvy* defaults to the first physical device numbered "0." To access a second physical disk, use the **-p 1** option.

The **-i** option specifies the device being divided will contain a **root** file system. With this option, device nodes are created relative to the new **root**, generally a hard disk, instead of the current **root**, often an installation floppy. If the name of a proto file is given after the **-i** option, a copy of this proto file is modified to fit the new file system, and passed to *mkfs*(C) when the new **root** file system is created. See *mkfs*(C) for information on proto files.

When *divvy* is invoked from the command line, you see a main menu:

d[isplay]	Display the divvy table.
b[lock]	Change the name of a division's block interface.
c[haracter]	Change the name of a division's character device.
o[verwrite]	Overwrite a division with a new file system.
p[revent]	Prevent a division from being overwritten.
s[tart]	Start a division on a new block.
e[nd]	End a division on a new block.
t[rade]	Trade the blocks two divisions refer to.
r[estore]	Restore default root partition table.

Please enter your choice or 'q' to quit:

To choose a command, enter the first letter of the command, then press RETURN. For example, to display the current division table, enter 'd'.

The *divvy* division table might look something like this:

Block Partition	Character Partition	Overwrite?	#	First Block	Last Block
root	rroot	no, exists	0	0	13754
swap	rswap	no, exists	1	13755	15135
u	ru	no, exists	2	15136	25135
recover	rrecover	no, exists	6	25136	25145
		no	3	-	-
		no	4	-	-
		no	5	-	-
d1057all	rd1057all	no	7	0	25546

When pertinent, *divvy* also displays information about block allocation for bad tracks.

If you select option 'b', you can change the name of a block division. *divvy* prompts you for the device number (from the *divvy* table displayed above), then for a new name. This is the same procedure for a character division.

Option 'o' selects a file system, or division, for overwriting when you exit from *divvy*. Notice that if you select an existing file system with the 'o' option, you see a 'yes' in the overwrite column. If you select option 'p,' the 'yes' changes to a 'no.'

With the 's' or 'start' command, you can start a division or file system on a new block number. You can start the division on any legal block, which includes:

- A block number less than the highest block on your disk.
- A block not already used by another division in this table.
- A block that is continuous with the rest of the division (does not span another block).

The same rules for 's' apply for the 'e' or 'end' command.

You can use these two commands to change the size of a partition. For example, if your disk is similar to the one in the example *divvy* table above, and you want to make the **root** file system smaller and the **swap** area larger, do this:

Make the **root** division smaller with the 's' command.

Increase the size of the swap area, using blocks freed from the **root** file system.

Note that when updating the *divvy* table you must update from back to front.

The 't' or 'trade' option switches the block size of two divisions. For example, you could trade **root** for **swap** in our example above. **root** would then be as large as **swap** and vice-versa.

The 'r' or 'restore' command restores a default **root** partition table. This is useful if you make a serious mistake and want to return from where you started.

When you exit from *divvy*, you are prompted whether you want to save any changes you made, or exit without saving the changes. At this time, you can also go back to the *divvy* menu, and you may have the option to reinstall the original, default partition table.

See Also

badtrk(M), **fdisk(C)**, **hd(M)**, **mkdev(C)**, **mkfs(C)**, **mknod(C)**

Notes

divvy requires kernel level support from the device driver. If *divvy* displays the messages:

cannot read division table

or

cannot get drive parameters

or lists the size of a disk as "0" blocks, the device may not support dividing. These errors may also occur if the prerequisite programs *fdisk* and *badtrk* are not completed correctly.

If you change the size of filesystems (such as **root** or **u**) after you have installed filesystem, you will have to run *mkfs* on the filesystem and reinstall the files that reside in that filesystem. This is because the free list for that filesystem has changed. Be sure to backup (using *backup(C)*, *tar(C)*, or *cpio(C)*) the files in any filesystem you intend to change before using *divvy*.

Name

`dmesg` - Displays the system messages on the console.

Syntax

`dmesg [-]`

Description

The *dmesg* command displays all the system messages that have been generated since the last time the system was booted. If the `-` option is specified, it displays only those messages that have been generated since the last time the *dmesg* command was performed.

dmesg is periodically invoked by the system according to the instructions in the file `/usr/lib/crontab`. It is also automatically invoked by the `/etc/rc` file whenever the system is booted.

A history of all system messages ever generated is recorded in `/usr/adm/messages`. This file will continue to grow unless the user occasionally erases its contents.

Files

`/etc/dmesg` `/etc/rc` `/usr/adm/messages` `/usr/adm/msgbuf`
`/usr/lib/crontab`

See Also

`cron(C)`

Name

dos, *doscat*, *doscp*, *dosdir*, *dosls*, *dosrm*, *dosrmdir* - Accesses DOS files.

Syntax

doscat [*-r*] *file* ...
doscp [*-r*] *file1 file2*
doscp [*-r*] *file* ... *directory*
dosdir *directory* ...
dosls *directory* ...
dosmkdir *directory* ...
dosrm *file* ...
dosrmdir *directory* ...

Description

The *dos* commands provide access to the files and directories on MS-DOS disks and on a DOS partition of the hard disk. The commands perform the following actions:

<i>doscat</i>	Copies one or more DOS files to the standard output. If <i>-r</i> is given, the files are copied without newline conversions (see "Conversions" below).
<i>doscp</i>	Copies files between an DOS disk and a XENIX file system. If <i>file1</i> and <i>file2</i> are given, <i>file1</i> is copied to <i>file2</i> . If a <i>directory</i> is given, one or more <i>files</i> are copied to that directory. If the <i>-r</i> is given, the files are copied without newline conversions (see "Conversions" below).
<i>dosdir</i>	Lists DOS files in the standard DOS style directory format.
<i>dosls</i>	Lists DOS directories and files in a XENIX style (see <i>ls(C)</i>).
<i>dosrm</i>	Removes files from an DOS disk.

dosmkdir Creates a directory on an DOS disk.

dosrmdir Deletes directories from an DOS disk.

The *file* and *directory* arguments for DOS files and directories have the form:

device:name

where *device* is a XENIX pathname for the special device file containing the DOS disk, and *name* is a pathname to a file or directory on the DOS disk. The two components are separated by a colon (:). For example, the argument:

/dev/fd0:/src/file.asm

specifies the DOS file, *file.asm*, in the directory, */src*, on the disk in the device file */dev/fd0*. Note that slashes (and not backslashes) are used as filename separators for DOS pathnames. Arguments without a *device*: are assumed to be XENIX files.

For convenience, the user configurable default file, */etc/default/msdos*, can define DOS drive names to be used in place of the special device file pathnames. It contains the following lines:

A=/dev/fd0 C=/dev/hd0d D=/dev/hd1d

The drive letter "A" may be used in place of special device file pathname */dev/fd0* when referencing DOS files (see "Examples" below). The drive letter "C" or "D" refer to the DOS partition on the first or second hard disk.

The commands operate on the following kinds of disks:

DOS partitions on a hard disk
5 1/4 inch DOS
8 or 9 sectors per track
40 tracks per side
1 or 2 sides
DOS version 1.0 or 2.0

Conversions

All DOS text files use a carriage-return/linefeed combination, CR-LF , to indicate a newline. XENIX uses a single newline LF character. When the *doscat* and *doscp* commands transfer DOS text files to XENIX , they automatically strip the CR.

When text files are transferred to DOS , the commands insert the CR before each LF character. The *-r* option can be used to override the automatic conversion and force the command to perform a true byte copy regardless of file type.

Examples

```
doscat /dev/fd0:/docs/memo.txt
doscat /tmp/f1 /tmp/f2 /dev/fd0:/src/file.asm

dosdir /dev/fd0:/src
dosdir A:/src A:/dev

doscp /tmp/myfile.txt /dev/fd0:/docs/memo.txt
doscp /tmp/f1 /tmp/f2 /dev/fd0:/mydir

dosls /dev/fd0:/src
dosls B:

dosmkdir /dev/fd0:/usr/docs

dosrm /dev/fd0:/docs/memo.txt
dosrm A:/docs/memo1.txt

dosrmdir /dev/fd0:/usr/docs
```

Files

/etc/default/msdos	Default information
/dev/fd*	Floppy disk devices
/dev/hd*	Hard disk devices

See Also

assign(C), dtype(C)

Notes

It is not possible to refer to DOS directories with wild card specifications. The programs mentioned above cooperate among themselves so no two programs will access the same DOS disk. Only one process will access a given DOS disk at any time, while other processes wait. If a process has to wait too long, it displays the error message, "can't seize a device," and exits with an exit code of 1.

The following hard disk devices:

/dev/hd0d	/dev/rhd0d	/dev/hd1d
/dev/rhd1d		

are similar to **/dev/hd0a** in that the disk driver determines which partition is the DOS partition and uses that as *hd?d*. This means that software using the DOS partition does not need to know which partition is DOS (the disk driver determines that).

The XENIX Development System supports the creation of DOS executable files, using *ccFR (CP)*. Refer to the *XENIX C User's Guide* and *C Library Guide* for more information on using XENIX to create programs suitable for DOS systems.

Name

`dtype` – Determines disk type.

Syntax

`dtype [-s] device ...`

Description

`dtype` determines type of disk, prints pertinent information on the standard output unless the silent (`-s`) option is selected, and exits with a corresponding code (see below). When more than one argument is given, the exit code corresponds to the last argument.

Disk Type	Exit Code	Message (optional)
Misc.	60	error (specified)
	61	empty or unrecognized data
Storage	70	dump format, volume n
	71	tar format[, extent e of n]
	72	cpio format
	73	cpio character (<code>-c</code>) format
MS-DOS	80	DOS 1.x, 8 sec/track, single sided
	81	DOS 1.x, 8 sec/track, dual sided
	90	DOS 2.x, 8 sec/track, single sided
	91	DOS 2.x, 8 sec/track, dual sided
	92	DOS 2.x, 9 sec/track, single sided
	93	DOS 2.x, 9 sec/track, dual sided
	94	DOS 2.x fixed disk
XENIX	120	XENIX 2.x filesystem [needs fsck]
	130	XENIX 3.x or later filesystem [needs fsck]
	140	XENIX 3.x or later word-swapped filesystem [needs fsck]

Notes

word-swapped refers to byte ordering of long words in relation to the host system.

XENIX file systems and dump and cpio binary formats may not be recognized if created on a foreign system. This is due to such system differences as byte and word swapping and structure alignment.

This utility only works reliably for floppy diskettes.

Name

`du` – Summarizes disk usage.

Syntax

`du [-afrsu] [names]`

Description

`du` gives the number of blocks contained in all files and (recursively) directories within each directory and file specified by the *names* argument. The block count includes the indirect blocks of the file. If *names* is missing, the current directory is used.

The optional argument `-s` causes only the grand total (for each of the specified *names*) to be given. The optional argument `-a` causes an entry to be generated for each file. Absence of either causes an entry to be generated for each directory only.

The `-f` option causes `du` to display the usage of files in the current file system only. Directories containing mounted file systems will be ignored. The `-u` option causes `du` to ignore files that have more than one link.

`du` is normally silent about directories that cannot be read, files that cannot be opened, etc. The `-r` option will cause `du` to generate messages in such instances.

A file with two or more links is only counted once.

Notes

If the `-a` option is not used, nondirectories given as arguments are not listed.

If there are too many distinct linked files, `du` will count the excess files more than once.

Files with holes in them will get an incorrect block count.

This utility reports sizes in 512 byte blocks. Systems which define a block as 1024 characters, “round-off” the size of files containing 511 or fewer bytes to 1 block. `du` interprets 1 block from a 1024 byte block system as 2 of its own 512 byte blocks. Thus a 500 byte file is interpreted as 2 blocks rather than 1. Refer to the **machine(HW)** manual page for the block size used by your system.

Name

dump – Performs incremental file system backup.

Syntax

dump [key [arguments] filesystem]

Description

dump copies to the specified device all files changed after a certain date in the *filesystem*. The *key* specifies the date and other options about the backup, where a *key* consists of characters from the set **0123456789kfusd**. The meanings of these characters are described below:

- f** Places the backup on the next *argument* file instead of the default device.
- u** If the backup completes successfully, writes the date of the beginning of the backup to the file */etc/ddate*. This file records a separate date for each file system and each backup level.
- 0-9** This number is the “backup level”. Backs up all files modified since the last date stored in the file */etc/ddate* for the same file system at lesser levels. If no date is determined by the level, the beginning of time is assumed; thus the option **0** causes the entire file system to be backed up.
- s** For backups to magnetic tape, the size of the tape specified in feet. The number of feet is taken from the next *argument*. When the specified size is reached, *dump* will wait for reels to be changed. The default size is 2,300 feet.
- d** For backups to magnetic tape, the density of the tape, expressed in BPI, is taken from the next *argument*. This is used in calculating the amount of tape used per write. The default is 1600.
- k** This option is used when backing up to a block-structured device, such as a floppy disk. The size (in K-bytes) of the volume being written is taken from the next *argument*. If the **k** argument is specified, any **s** and **d** arguments are ignored. The default is to use **s** and **d**.

If no arguments are given, the *key* is assumed to be **9u** and a default file system is backed up to the default device.

The first backup should be a full level-0 backup:

```
dump 0u
```

Next, periodic level 9 backups should be made on an exponential progression of tapes or floppies:

```
dump 9u
```

This progression is shown as follows:

```
1 2 1 3 1 2 1 4 ...
```

where backup 1 is used every other time, backup 2 every fourth, backup 3 every eighth, etc.) When the level-9 incremental backup becomes unmanageable because a tape is full or too many floppies are required, a level-1 backup should be made:

```
dump 1u
```

After this, the exponential series should progress as if uninterrupted. These level-9 backups are based on the level-1 backup, which is based on the level-0 full backup. This progression of levels of backups can be carried as far as desired.

The default file system and the backup device depend on the settings of the variables DISK and TAPE, respectively, in the file `/etc/default/dump`.

Files

<code>/etc/ddate</code>	Records backup dates of file system/level
<code>etc/default/dump</code>	Default dump information

See Also

XENIX Operations Guide
`cpio(C)`, `default(M)`, `dumpdir(C)`, `restore(C)`, `dump(F)`

Diagnostics

If the backup requires more than one volume (where a volume is likely to be a floppy disk or tape), you will be asked to change volumes. Press RETURN after changing volumes.

Notes

Sizes are based on 1600 BPI for blocked tape; the raw magnetic tape device has to be used to approach these densities. Write errors to the backup device are usually fatal. Read errors on the file system are ignored.

It is not possible to successfully *restore* an entire active root file system.

Warning

When backing up to floppy disks, be sure to have enough *formatted* floppies ready before starting a backup.

Name

dumpdir – Prints the names of files on a backup archive.

Syntax

dumpdir [**f** filename]

Description

dumpdir is used to list the names and inode numbers of all files and directories on an archive written with the *backup* command. This is most useful when attempting to determine the location of a particular file in a set of backup archives.

The **f** option causes *filename* to be used as the name of the backup device instead of the default. The backup device depends on the setting of the variable TAPE in the file */etc/default/dumpdir*. The device specified as TAPE can be any type of backup device supported by the system (for example, a floppy drive or cartridge tape drive).

Files

rst* Temporary files

See Also

backup(C), restore(C), default(M)

Diagnostics

If the backup extends over more than one volume (where a volume is likely a floppy disk or tape), you will be asked to change volumes. Press RETURN after changing volumes.

Name

echo – Echoes arguments.

Syntax

```
echo [ arg ] ...  
/bin/echo [ arg ] ...
```

Description

echo writes its arguments separated by blanks and terminated by a newline on the standard output. *echo* also understands C-like escape conventions. The following escape sequences need to be quoted so that the shell interprets them correctly:

\b Backspace

\c Prints line without newline

\f Form feed

\n Newline

\r Carriage return

\t Tab

\v Vertical tab

**** Backslash

\n The 8-bit character whose ASCII code is the 1, 2 or 3-digit octal number *n* must start with a zero

echo is useful for producing diagnostics in command files and for sending known data into a pipe.

See Also

sh(C)

Notes

The *cs**h*(C) has a built-in *echo* utility which has a different syntax than this *echo*. Be aware that users running under *cs**h* will get the built-in *echo* unless they specify */bin/echo* .

Name

ed - Invokes the text editor.

Syntax

ed [-] [-p string] [file]

Description

ed is the standard text editor. If the *file* argument is given, *ed* simulates an *e* command (see below) on the named file; that is to say, the file is read into *ed*'s buffer so that it can be edited. *ed* operates on a copy of the file it is editing; changes made to the copy have no effect on the file until a *w* (write) command is given. The copy of the text being edited resides in a temporary file called the *buffer*. There is only one buffer.

The options are:

- Suppresses the printing of character counts by the *e*, *r*, and *w* commands, of diagnostics from *e* and *q* commands, and the ! prompt after a *!shell command*.
- p Allows the user to specify a prompt string.

ed supports formatting capability. After including a format specification as the first line of *file* and invoking *ed* with your terminal in *stty -tabs* or *stty tab3* mode (see *stty*(C)), the specified tab stops will automatically be used when scanning *file*. For example, if the first line of a file contained:

```
<:t5,10,15 s72:>
```

tab stops would be set at columns 5, 10, and 15, and a maximum line length of 72 would be imposed. NOTE: While inputting text, tab characters are expanded to every eighth column as the default.

Commands to *ed* have a simple and regular structure: zero, one, or two *addresses* followed by a single-character *command*, possibly followed by parameters to that command. These addresses specify one or more lines in the buffer. Every command that requires addresses has default addresses, so that the addresses can very often be omitted.

In general, only one command may appear on a line. Certain commands allow the input of text. This text is placed in the appropriate place in the buffer. While *ed* is accepting text, it is said to be in *input mode*. In this mode, *no* commands are recognized; all input is merely collected. Input mode is left by entering a period (.) alone at the beginning of a line.

ed supports a limited form of *regular expression* notation; regular expressions are used in addresses to specify lines and in some commands (e.g., *s*) to specify portions of a line that are to be substituted. A regular expression specifies a set of character strings. A member of this set of strings is said to be *matched* by the regular expression. The regular expressions allowed by *ed* are constructed as follows:

The following one-character regular expressions match a *single* character:

- 1.1 An ordinary character (*not* one of those discussed in 1.2 below) is a one-character regular expression that matches itself.
- 1.2 A backslash (\) followed by any special character is a one-character regular expression that matches the special character itself. The special characters are:
 - a. ., *, [, and \ (dot, star, left square bracket, and backslash, respectively), which are always special, *except* when they appear within square brackets ([]; see 1.4 below).
 - b. ^ (caret), which is special at the *beginning* of an *entire* regular expression (see 3.1 and 3.2 below), or when it immediately follows the left of a pair of square brackets ([]) (see 1.4 below).
 - c. \$ (dollar sign), which is special at the *end* of an entire regular expression (see 3.2 below).
 - d. The character used to bound (i.e., delimit) an entire regular expression, which is special for that regular expression (for example, see how slash (/) is used in the *g* command below).
- 1.3 A period (.) is a one-character regular expression that matches any character except newline.
- 1.4 A nonempty string of characters enclosed in square brackets ([]) is a one-character regular expression that matches *any one* character in that string. If, however, the first character of the string is a caret (^), the one-character regular expression matches any character *except* newline and the remaining

characters in the string. The star (*) has this special meaning *only* if it occurs first in the string. The dash (–) may be used to indicate a range of consecutive ASCII characters; for example, [0–9] is equivalent to [0123456789]. The dash (–) loses this special meaning if it occurs first (after an initial caret (^), if any) or last in the string. The right square bracket (]) does not terminate such a string when it is the first character within it (after an initial caret (^), if any); e.g., [ja–f] matches either a right square bracket (]) or one of the letters “a” through “f” inclusive. Dot, star, left bracket, and the backslash lose their special meaning within such a string of characters.

The following rules may be used to construct regular expressions from one-character regular expressions:

- 2.1 A one-character regular expression matches whatever the one-character regular expression matches.
- 2.2 A one-character regular expression followed by a star (*) is a regular expression that matches *zero* or more occurrences of the one-character regular expression. If there is any choice, the longest leftmost string that permits a match is chosen.
- 2.3 A one-character regular expression followed by $\{m\}$, $\{m,\}$, or $\{m,n\}$ is a regular expression that matches a *range* of occurrences of the one-character regular expression. The values of m and n must be nonnegative integers less than 255; $\{m\}$ matches *exactly* m occurrences; $\{m,\}$ matches *at least* m occurrences; $\{m,n\}$ matches any number of occurrences between m and n , inclusive. Whenever a choice exists, the regular expression matches as many occurrences as possible.
- 2.4 The concatenation of regular expressions is a regular expression that matches the concatenation of the strings matched by each component of the regular expression.
- 2.5 A regular expression enclosed between the character sequences \ (and \) is a regular expression that matches whatever the unadorned regular expression matches. See 2.6 below for a discussion of why this is useful.
- 2.6 The expression $\backslash n$ matches the same string of characters as was matched by an expression enclosed between \ (and \) *earlier* in the same regular expression. Here n is a digit; the subexpression specified is that beginning with the n -th occurrence of \ (counting from the left. For example, the expression $\backslash (.*) \backslash 1 \$$ matches a line consisting of two repeated appearances of the same string.

Finally, an *entire regular expression* may be constrained to match only an initial segment or final segment of a line (or both):

- 3.1 A caret (^) at the beginning of an entire regular expression constrains that regular expression to match an *initial* segment of a line.
- 3.2 A dollar sign (\$) at the end of an entire regular expression constrains that regular expression to match a *final* segment of a line. The construction *^entire regular expression\$* constrains the entire regular expression to match the entire line.

The null regular expression (e.g., *//*) is equivalent to the last regular expression encountered.

To understand addressing in *ed*, it is necessary to know that there is a *current line* at all times. Generally speaking, the current line is the last line affected by a command; the exact effect on the current line is discussed under the description of each command. *Addresses* are constructed as follows:

1. The character *.* addresses the current line.
2. The character *\$* addresses the last line of the buffer.
3. A decimal number *n* addresses the *n*-th line of the buffer.
4. *'x* addresses the line marked with the mark name character *x*, which must be a lowercase letter. Lines are marked with the *k* command described below.
5. A regular expression enclosed by slashes (*/*) addresses the first line found by searching *forward* from the line *following* the current line toward the end of the buffer and stopping at the first line containing a string matching the regular expression. If necessary, the search wraps around to the beginning of the buffer and continues up to and including the current line, so that the entire buffer is searched.
6. A regular expression enclosed in question marks (?) addresses the first line found by searching *backward* from the line *preceding* the current line toward the beginning of the buffer and stopping at the first line containing a string matching the regular expression. If necessary, the search wraps around to the end of the buffer and continues up to and including the current line. See also the last paragraph before *Files* below.
7. An address followed by a plus sign (+) or a minus sign (-) followed by a decimal number specifies that address plus or minus the indicated number of lines. The plus sign may be omitted.

8. If an address begins with **+** or **-**, the addition or subtraction is taken with respect to the current line; e.g., **-5** is understood to mean **.-5**.
9. If an address ends with **+** or **-**, then 1 is added to or subtracted from the address, respectively. As a consequence of this rule and of rule 8 immediately above, the address **-** refers to the line preceding the current line. (To maintain compatibility with earlier versions of the editor, the character **^** in addresses is entirely equivalent to **-**.) Moreover, trailing **+** and **-** characters have a cumulative effect, so **--** refers to the current line less 2.
10. For convenience, a comma (,) stands for the address pair **1,\$**, while a semicolon (;) stands for the pair **.,\$**.

Commands may require zero, one, or two addresses. Commands that require no addresses regard the presence of an address as an error. Commands that accept one or two addresses assume default addresses when an insufficient number of addresses is given; if more addresses are given than such a command requires, the last address(es) are used.

Typically, addresses are separated from each other by a comma (,). They may also be separated by a semicolon (;). In the latter case, the current line (.) is set to the first address, and only then is the second address calculated. This feature can be used to determine the starting line for forward and backward searches (see rules 5 and 6 above). The second address of any two-address sequence must correspond to a line that follows, in the buffer, the line corresponding to the first address.

In the following list of *ed* commands, the default addresses are shown in parentheses. The parentheses are *not* part of the address; they show that the given addresses are the default.

It is generally illegal for more than one command to appear on a line. However, any command (except *e*, *f*, *r*, or *w*) may be suffixed by **p** or by **l**, in which case the current line is either printed or listed, respectively, as discussed below under the *p* and *l* commands.

(.)a
<text>

The *append* command reads the given text and appends it after the addressed line; dot is left at the last inserted line, or, if there were no inserted lines, at the addressed line. Address 0 is legal for this command: it causes the "appended" text to be placed at the beginning of the buffer.

(.)c
 <text>
 .
 The

change command deletes the addressed lines, then accepts input text that replaces these lines; dot is left at the last line input, or, if there were none, at the first line that was not deleted.

(.,.)d

The *delete* command deletes the addressed lines from the buffer. The line after the last line deleted becomes the current line; if the lines deleted were originally at the end of the buffer, the new last line becomes the current line.

e *file*

The *edit* command causes the entire contents of the buffer to be deleted, and then the named file to be read in; dot is set to the last line of the buffer. If no filename is given, the currently remembered filename, if any, is used (see the *f* command). The number of characters read is typed; *file* is remembered for possible use as a default filename in subsequent *e*, *r*, and *w* commands. If *file* begins with an exclamation (!), the rest of the line is taken to be a shell command. The output of this command is read for the *e* and *r* commands. For the *w* command, the file is used as the standard input for the specified command. Such a shell command is *not* remembered as the current filename.

E *file*

The *Edit* command is like *e*, except the editor does not check to see if any changes have been made to the buffer since the last *w* command.

f *file*

If *file* is given, the *f* filename command changes the currently remembered filename to *file*; otherwise, it prints the currently remembered filename.

(1,\$)g/*regular-expression*/*command list*

In the *global* command, the first step is to mark every line that matches the given regular expression. Then, for every such line, the given *command list* is executed with . initially set to that line. A single command or the first of a list of commands appears on the same line as the global command. All lines of a multiline list except the last line must be ended with a \; *a*, *i*, and *c* commands and associated input are permitted; the . terminating input mode may be omitted if it would be the last line of the *command list*. An empty *command list* is equivalent to the *p* command. The *g*, *G*, *v*, and *V* commands are *not* permitted in the *command list*. See also *Notes* and the last paragraph before *Files* below.

(1,\$)G/regular-expression/

In the interactive *G*lobal command, the first step is to mark every line that matches the given regular expression. Then, for every such line, that line is printed, dot (.) is changed to that line, and any *one* command (other than one of the *a*, *c*, *i*, *g*, *G*, *v*, and *V* commands) may be input and is executed. After the execution of that command, the next marked line is printed, and so on; a newline acts as a null command; an ampersand (&) causes the re-execution of the most recent command executed within the current invocation of *G*. Note that the commands input as part of the execution of the *G* command may address and affect *any* lines in the buffer. The *G* command can be terminated by entering an INTERRUPT.

h

The *help* command gives a short error message that explains the reason for the most recent ? diagnostic.

H

The *Help* command causes *ed* to enter a mode in which error messages are printed for all subsequent ? diagnostics. It will also explain the previous diagnostic if there was one. The *H* command alternately turns this mode on and off; it is initially on.

(.)i

<text>

The *insert* command inserts the given text before the addressed line; dot is left at the last inserted line, or if there were no inserted lines, at the addressed line. This command differs from the *a* command only in the placement of the input text. Address 0 is not legal for this command.

(.,.+1)j

The *join* command joins contiguous lines by removing the appropriate newline characters. If only one address is given, this command does nothing.

(.)kx

The *mark* command marks the addressed line with name *x*, which must be a lowercase letter. The address *x* then addresses this line; dot is unchanged.

(.,.)l

The *list* command prints the addressed lines in an unambiguous way: a few nonprinting characters (e.g., tab, backspace) are represented by mnemonic overstrikes, all other nonprinting characters are printed in octal, and long lines are folded. An *l* command may be appended to any command other than *e*, *f*, *r*, or *w*.

(.,.)ma

The *move* command repositions the addressed line(s) after the line addressed by *a*. Address 0 is legal for *a* and causes the addressed line(s) to be moved to the beginning of the file; it is an error if address *a* falls within the range of moved lines; dot is left at the last line moved.

(.,.)n

The *number* command prints the addressed lines, preceding each line by its line number and a tab character; dot is left at the last line printed. The *n* command may be appended to any command other than *e*, *f*, *r*, or *w*.

(.,.)p

The *print* command prints the addressed lines; dot is left at the last line printed. The *p* command may be appended to any command other than *e*, *f*, *r*, or *w*; for example, *dp* deletes the current line and prints the new current line.

P

The editor will prompt with a * for all subsequent commands. The *P* command alternately turns this mode on and off; it is initially on.

q

The *quit* command causes *ed* to exit. No automatic write of a file is done.

Q

The editor exits without checking if changes have been made in the buffer since the last *w* command.

(\$)r file

The *read* command reads in the given file after the addressed line. If no filename is given, the currently remembered filename, if any, is used (see *e* and *f* commands). The currently remembered filename is *not* changed unless *file* is the very first filename mentioned since *ed* was invoked. Address 0 is legal for *r* and causes the file to be read at the beginning of the buffer. If the read is successful, the number of characters read is typed; dot is set to the last line read in. If *file* begins with *!*, the rest of the line is taken to be a shell (*sh*(C)) command whose output is to be read. Such a shell command is *not* remembered as the current filename.

(.,.)s/regular-expression/replacement/ or

(.,.)s/regular-expression/replacement/g or

(.,.)s/regular-expression/replacement/n n=1-512

The substitute command searches each addressed line for an occurrence of the specified regular expression. In each line in which a match is found, all (nonoverlapped) matched strings are replaced by the *replacement* if the global replacement indicator *g* appears after the command. If the global indicator does not appear, only the first occurrence of the matched string is replaced. It is an error for the substitution to fail on *all* addressed lines. Any character other than space or newline may be used instead of */* to delimit the regular expression and the *replacement*; dot is left at the last line on which a substitution occurred.

An ampersand (&) appearing in the *replacement* is replaced by the string matching the regular expression on the current line. The special meaning of the ampersand in this context may be suppressed by preceding it with a backslash. The characters *\n*, where *n* is a digit, are replaced by the text matched by the *n*-th regular subexpression of the specified regular expression enclosed between *\(* and *\)*. When nested parenthesized subexpressions are present, *n* is determined by counting occurrences of *\(* starting from the left. When the character *%* is the only character in the *replacement*, the *replacement* used in the most recent substitute command is used as the *replacement* in the current substitute command. The *%* loses its special meaning when it is in a replacement string of more than one character or is preceded by a **.

A line may be split by substituting a newline character into it. The newline in the *replacement* must be escaped by preceding it with a **. Such a substitution cannot be done as part of a *g* or *v* command list.

(.,.)*ta*

This command acts just like the *m* command, except that a copy of the addressed lines is placed after address *a* (which may be 0); dot is left at the last line of the copy.

u

The *undo* command nullifies the effect of the most recent command that modified anything in the buffer, namely the most recent *a*, *c*, *d*, *g*, *i*, *j*, *m*, *r*, *s*, *t*, *v*, *G*, or *V* command.

(1,\$)*v*/*regular-expression*/*command list*

This command is the same as the global command *g* except that the *command list* is executed with dot initially set to every line that does *not* match the regular expression.

(1,\$)*V*/*regular-expression*/

This command is the same as the interactive global command *G* except that the lines that are marked during the first step are those that do *not* match the regular expression.

(1,\$)w file

The *w*rite command writes the addressed lines into the named file. If the file does not exist, it is created with mode 666 (readable and writable by everyone), unless the *umask* setting (see *sh(C)*) dictates otherwise. The currently remembered filename is *not* changed unless *file* is the very first filename mentioned since *ed* was invoked. If no filename is given, the currently remembered filename, if any, is used (see *e* and *f* commands); dot is unchanged. If the command is successful, the number of characters written is displayed. If *file* begins with an exclamation (!), the rest of the line is taken to be a shell command to which the addressed lines are supplied as the standard input. Such a shell command is *not* remembered as the current filename.

(\$)=

The line number of the addressed line is typed; dot is unchanged by this command.

!shell command

The remainder of the line after the ! is sent to the XENIX shell (*sh(C)*) to be interpreted as a command. Within the text of that command, the unescaped character % is replaced with the remembered filename; if a ! appears as the first character of the shell command, it is replaced with the text of the previous shell command. Thus, !! will repeat the last shell command. If any expansion is performed, the expanded line is echoed; dot is unchanged.

(.+1)

An address alone on a line causes the addressed line to be printed. A RETURN alone on a line is equivalent to **.+1p**. This is useful for stepping forward through the editing buffer a line at a time.

If an interrupt signal (ASCII DEL or BREAK) is sent, *ed* prints a question mark (?) and returns to its command level.

Some size limitations: 512 characters per line, 256 characters per global command list, 64 characters per filename, and 128K characters in the buffer. The limit on the number of lines depends on the amount of user memory.

When reading a file, *ed* discards ASCII NUL characters and all characters after the last newline. Files (e.g., **a.out**) that contain characters not in the ASCII set (bit 8 on), cannot be edited by *ed*.

If the closing delimiter of a regular expression or of a replacement string (e.g., /) would be the last character before a newline, that delimiter may be omitted, in which case the addressed line is printed. Thus, the following pairs of commands are equivalent:

```
s/s1/s2s/s1/s2/p
g/s1g/s1/p
?s1?s1?
```

Files

/tmp/e# Temporary; # is the process number

ed.hup Work is saved here if the terminal is hung up

See Also

grep(C), sed(C), sh(C), stty(C), regexp(S)

Diagnostics

? Command errors
? *file* An inaccessible file

Use the *help* and *Help* commands for detailed explanations.

If changes have been made in the buffer since the last *w* command that wrote the entire buffer, *ed* warns the user if an attempt is made to destroy *ed*'s buffer via the *e* or *q* commands: it prints ? and allows you to continue editing. A second *e* or *q* command at this point will take effect. The dash (-) command-line option inhibits this feature.

Notes

An exclamation (!) command cannot be subject to a *g* or a *v* command.

The ! command and the ! escape from the *e*, *r*, and *w* commands cannot be used if the editor is invoked from a restricted shell (see *sh*(C)).

The sequence \n in a regular expression does not match any character.

The *l* command mishandles DEL.

Because 0 is an illegal address for the *w* command, it is not possible to create an empty file with *ed*.

Characters are mashed to 7 bits on input.

If the editor input is coming from a command file (i.e., *ed file < ed-cmd-file*), the editor will exit at the first failure of a command in the command file.

Name

enable – Turns on terminals and line printers.

Syntax

enable tty ...
enable printers

Description

For terminals this program manipulates the */etc/ttys* file and signals *init* to allow logins on a particular terminal.

For line printers, *enable* activates the named printers and enables them to print requests taken by *lp(C)*. Use *lpstat(C)* to find the status of the printers.

Examples

A simple command to enable **tty01** follows:

```
enable tty01
```

Files

*/dev/tty**
/etc/ttys
*/usr/spool/lp/**

See Also

disable(C), *getty(M)*, *init(M)*, *login(M)*, *lp(C)*, *lpstat(C)*, *ttys(M)*

Warning

Be absolutely certain to pause at least *one minute* before reusing this command or before using the *disable* command. Failure to do so may cause the system to crash.

Name

`env` – Sets environment for command execution.

Syntax

`env [-] [name=value] ... [command args]`

Description

env obtains the current *environment*, modifies it according to its arguments, then executes the command with the modified environment. Arguments of the form *name=value* are merged into the inherited environment before the command is executed. The `-` flag causes the inherited environment to be ignored completely, so that the command is executed with exactly the environment specified by the arguments.

If no command is specified, the resulting environment is printed, one name-value pair per line.

See Also

`sh(C)`, `exec(S)`, `profile(F)`, `environ(M)`

Notes

The 2.3 *printenv* command has been replaced in XENIX 3.0 and System V by the *env* command. The *printenv* shipped is a link to the command *env*.

Name

ex – Invokes a text editor.

Syntax

ex [-] [-v] [-t tag] [-r] [+lineno] name ...

Description

ex is the root of the editors *ex* and *vi*. *ex* is a superset of *ed*, whose most notable extension is a display editing facility. Display based editing is the focus of *vi*.

If you have not used *ed*, or if you are a casual user, you will find that *edit* is most convenient for you. It avoids some of the complexities of *ex* which is used mostly by systems programmers and persons very familiar with *ed*.

If you have a CRT terminal, you may wish to use a display based editor; in this case see *vi*(C), a command which focuses on the display editing portion of *ex*.

For ed Users

If you have used *ed* you will find that *ex* has a number of new features. Intelligent terminals and high-speed terminals are very pleasant to use with *vi*. Generally, the *ex* editor uses far more of the capabilities of terminals than *ed* does. It uses the terminal capability database *termcap* (M) and the type of the terminal you are using from the variable *TERM* in the environment to determine how to drive your terminal efficiently. The *ex* editor makes use of features such as insert and delete character and line in its **visual** command mode, which can be abbreviated **vi**, which is the central mode of editing when using *vi*(C). There is also an interline editing **open** command, (**o**) that works on all terminals.

ex contains a number of features for easily viewing the text of a file. The **z** command gives easy access to windows of text. Hitting Ctrl-D causes the editor to scroll a half-window of text and is more useful for quickly stepping through a file than just hitting the RETURN key. Of course, the screen-oriented **visual** mode gives constant access to editing context.

ex gives you more help when you make mistakes. The **undo (u)** command allows you to reverse any single change. *ex* gives you a lot of feedback, normally printing changed lines, and indicates when more than a few lines are affected by a command so it is easy to detect when a command has affected more lines than it should have.

The editor also normally prevents the overwriting of existing files unless you have edited them, so that you do not accidentally clobber with a *write* a file other than the one you are editing. If the system (or editor) crashes, or you accidentally hang up the phone, you can use the **recover** command to retrieve your work. This will get you back to within a few lines of where you left off.

ex has several features for editing more than one file at a time. You can give it a list of files on the command line and use the **next (n)** command to edit each in turn. You can also give the **next** command a list of filenames, or a pattern used by the shell to specify a new set of files to be edited. In general, filenames in the editor may be formed with full shell metasyntax. The metacharacter “%” is also available in forming filenames and is replaced by the name of the current file. For editing large groups of related files, you can use *ex*’s **tag** command to quickly locate functions and other important points in any of the files. This is useful when you want to find the definition of a particular function in a large program. The command **ctags(CP)** builds a *tags* file or a group of C programs.

For moving text between files and within a file, the editor has a group of buffers named *a* through *z*. You can place text in these named buffers and carry it over when you edit another file.

The command **&** repeats the last **substitute** command. There is also a confirmed substitute command. You give a range of substitutions to be done and the editor interactively prompts you whether each substitution is desired.

You can use the **substitute** command in *ex* to systematically convert the case of letters between uppercase and lowercase. It is possible to ignore case in searches and substitutions. *ex* also allows regular expressions that match words to be constructed. This is convenient, for example, when searching for the word “edit” if your document also contains the word “editor.”

ex has a set of *options* that you can set. One option which is very useful is the *autoindent* option that allows the editor to automatically supply leading white space to align text. You can then press Ctrl-D to backtab, space and tab forward to align new code easily.

Miscellaneous new useful features include an intelligent **join (j)** command which supplies whitespace between joined lines automatically, the commands **<** and **>** which shift groups of lines, and the

ability to filter portions of the buffer through commands such as *sort*.

Files

/usr/preserve	Preservation directory

See Also

awk(C), ctags(CP), cd(C), grep(C), sed(C), termcap(M), vi(C)

Credit

This utility was developed at the University of California at Berkeley and is used with permission.

Notes

The *undo* command causes all marks to be lost on lines changed and then restored if the marked lines were changed.

Undo never clears the buffer modified condition.

The *z* command prints a number of logical rather than physical lines. More than a screen full of output may result if long lines are present.

File input/output errors don't print a name if the command line "*-*" option is used.

There is no easy way to do a single scan ignoring case.

Because of the implementation of the arguments to *next*, only 512 bytes of argument list are allowed there.

The format of **/etc/termcap** and the large number of capabilities of terminals used by the editor cause terminal type setup to be rather slow.

The editor does not warn if text is placed in named buffers and not used before exiting the editor.

Null characters are discarded in input files and cannot appear in resultant files.

Name

expr – Evaluates arguments as an expression.

Syntax

expr arguments

Description

The arguments are taken as an expression. After evaluation, the result is written on the standard output. Terms of the expression must be separated by blanks. Characters special to the shell must be escaped. Note that zero is returned to indicate a zero value, rather than the null string. Strings containing blanks or other special characters should be quoted. Integer-valued arguments may be preceded by a unary minus sign. Internally, integers are treated as 32-bit, 2's complement numbers.

The operators and keywords are listed below. Expressions should be quoted by the shell, since many of the characters that have special meaning in the shell also have special meaning in *expr*. The list is in order of increasing precedence, with equal precedence operators grouped within braces ({ and }).

expr | *expr*

Returns the first *expr* if it is neither null nor 0, otherwise returns the second *expr*.

expr & *expr*

Returns the first *expr* if neither *expr* is null nor 0, otherwise returns 0.

expr { =, >, >=, <, <=, != } *expr*

Returns the result of an integer comparison if both arguments are integers, otherwise returns the result of a lexical comparison.

expr { +, - } *expr*

Addition or subtraction of integer-valued arguments.

expr { *, /, % } *expr*

Multiplication, division, or remainder of the integer-valued arguments.

expr : *expr*

The matching operator : compares the first argument with the second argument which must be a regular expression; regular expression syntax is the same as that of *ed*(C), except that all patterns are “anchored” (i.e., begin with a caret (^))

and therefore the caret is not a special character in that context. (Note that in the shell, the caret has the same meaning as the pipe symbol (|).) Normally the matching operator returns the number of characters matched (zero on failure). Alternatively, the `\(...\)` pattern symbols can be used to return a portion of the first argument.

Examples

1. `a=`expr $a + 1``

Adds 1 to the shell variable `a`.

2. `# For $a equal to either "/usr/abc/file" or just "/file"`
`'expr $a : .*\/(.*\)|$a'`

Returns the last segment of a pathname (i.e., file). Watch out for the slash alone as an argument: *expr* will take it as the division operator (see *Notes* on the next page).

3. `expr $VAR : `.*``

Returns the number of characters in `$VAR`.

See Also

`ed(C)`, `sh(C)`

Diagnostics

As a side effect of expression evaluation, *expr* returns the following exit values:

- | | |
|---|--|
| 0 | If the expression is neither null nor zero |
| 1 | If the expression is null or zero |
| 2 | For invalid expressions |

Other diagnostics include:

syntax error For operator/operand errors

nonnumeric argument
 If arithmetic is attempted on such a string

Notes

After argument processing by the shell, *expr* cannot tell the difference between an operator and an operand except by the value. If **\$a** is an equals sign (=), the command:

```
expr $a = =
```

looks like:

```
expr = = =
```

Thus the arguments are passed to *expr* (and will all be taken as the = operator). The following permits comparing equals signs:

```
expr X$a = X=
```

Name

`factor` – Factor a number.

Syntax

`factor` [number]

Description

When *factor* is invoked without an argument, it waits for a number to be typed in. If you type in a positive number less than 2^{46} (about 7.2×10^{13}) it will factor the number and print its prime factors; each one is printed the proper number of times. Then it waits for another number. It exits if it encounters a zero or any non-numeric character.

If *factor* is invoked with an argument, it factors the number as above and then exits.

The time it takes to factor a number, n , is proportional to \sqrt{n} . It usually takes longer to factor a prime or the square of a prime, than to factor other numbers.

Diagnostics

factor returns an error message if the supplied input value is greater than 2^{46} or is not an integer number.

Name

false – Returns with a nonzero exit value.

Syntax

false

Description

false does nothing except return with a nonzero exit value. *true*(C), *false*'s counterpart, does nothing except return with a zero exit value. "False" is typically used in shell procedures such as:

```
until false
do
    command
done
```

See Also

sh(C), true(C)

Diagnostics

false is any non-zero value.

Name

fdisk – Maintain disk partitions.

Syntax

fdisk [-f device]

Description

fdisk displays information about disk partitions. *fdisk* also creates and deletes disk partitions and changes the active partition. *fdisk* functionality is a superset of the MS-DOS command of the same name. *fdisk* is used interactively from a menu.

The hard disk has four partitions. Only one partition is active at any given time. It is possible to assign a different operating system to each partition. Once a partition is made active, the operating system resident in that partition boots automatically once the current operating system is halted.

To use XENIX, at least one partition must be assigned to XENIX.

The *fdisk* utility does not allocate the last track on the hard disk unless the “Use Entire Disk for XENIX” option is used. The “Create XENIX Partition” option always leaves the last track unsigned.

For example, if a disk has 2442 tracks, *fdisk* reports these as tracks 0-2441. It will assign (using the “Create XENIX Partition” option) tracks 1-2440. Track 0 is reserved. Track 2441 is only assigned with the “Use Entire Disk for XENIX” option.

Partitions are defined by a “partition table” at the end of the master boot block. The partition table provides the location and size of the partitions on the disk. The partition table also defines the active partition. Each partition can be assigned to XENIX, DOS, or some other operating system. Once a DOS partition is set up, DOS files and directories resident in the DOS partition may be accessed while running XENIX by means of the *dos(C)* commands. DOS may be booted without the DOS partition being active via the “boot:dos” command. See *boot(HW)*.

Arguments

-f *name*

Open device *name* and read the partition table associated with that device's partition. The default is */dev/hd00*.

Options

The *fdisk* command displays a prompt and a menu of five options. Updates to the disk are not made until you confirm at exit.

1. Display Partition Table.

This option displays a table of information about each partition on the hard disk. The PARTITION column gives the partition number. The STATUS column tells whether the partition is active (A) or inactive (I). TYPE tells whether the partition is XENIX, DOS, or "other". The option also displays the starting track, ending track and total number of tracks in each partition.

2. Use Entire Disk for XENIX.

fdisk creates one partition that includes all the tracks on the disk. This partition is assigned to XENIX and is designated the active partition.

3. Create XENIX Partition

This option allows the creation of a partition by altering the partition table. *fdisk* reports the number of tracks available for each partition and the number of tracks in use. *fdisk* prompts for the partition to create, the starting track and size in tracks. The change is not made until confirmation upon exit.

4. Activate XENIX Partition

This option changes the active partition. Only one partition may be active at a time. The change is not effective until confirmation upon exit. The operating system residing in the newly activated partition boots once the current operating system is halted.

5. Delete XENIX Partition

This option requests which partition you wish to delete. *fdisk* reports the new available amount of disk space in tracks. The change is not effective until confirmation upon exit.

Exit the *fdisk* program by typing a 'q' at the main *fdisk* menu. *fdisk* asks for confirmation before it updates the changes to the hard disk partition table. If you answer 'y' for yes, the changes are made. If you answer 'n' for no, the changes are not made and *fdisk* exits.

Notes

The minimum recommended size for a XENIX partition is 6 megabytes.

Since *fdisk* is intended for use with DOS, it may not work with all operating system combinations.

FDISK (C)

FDISK (C)

See also

dos(C), hd(M).

Name

file - Determines file type.

Syntax

file [**-m**] *file* ...

file [**-m**] **-f** *namesfile*

Description

file performs a series of tests on each argument in an attempt to classify it. If an argument appears to be ASCII, *file* examines the first 512 bytes and tries to guess its language.

If the **-f** option is given, *file* takes the list of filenames from *namesfile*. If the **-m** option is given, *file* sets the access time for the examined file to the current time. Otherwise, the access time remains unchanged.

Several object file formats are recognized. For **a.out** and **x.out** format object files, the relationship of *cc* flags to file classification is **-i** for "separate", **-n** for "pure", and **-s** for not "not stripped."

Credit

This utility was developed at the University of California at Berkeley and is used with permission.

Notes

It can make mistakes: in particular it often mistakes command files for C programs.

Name

find – Finds files.

Syntax

find pathname-list expression

Description

find recursively descends the directory hierarchy for each pathname in the *pathname-list* (i.e., one or more pathnames) seeking files that match a Boolean *expression* written in the primaries given below. In the descriptions, the argument *n* is used as a decimal integer where *+n* means more than *n*, *-n* means less than *n* and *n* means exactly *n*.

- name *file*** True if *file* matches the current file name. Normal shell argument syntax may be used if escaped (watch out for the left bracket ([), the question mark (?) and the star (*).
- perm *onum*** True if the file permission flags exactly match the octal number *onum* (see *chmod(C)*). If *onum* is prefixed by a minus sign, more flag bits (017777, see *stat(S)*) become significant and the flags are compared.
- type *x*** True if the type of the file is *x*, where *c* is **b**, **c**, **d**, **p**, or **f** for block special file, character special file, directory, first-in-first-out, or plain file respectively.
- links *n*** True if the file has *n* links.
- user *uname*** True if the file belongs to the user *uname*. If *uname* is numeric and does not appear as a login name in the */etc/passwd* file, it is taken as a user ID.
- group *gname*** True if the file belongs to the group *gname*. If *gname* is numeric and does not appear in the */etc/group* file, it is taken as a group ID.
- size *n*** True if the file is *n* blocks long (512 bytes per block).
- atime *n*** True if the file has been accessed in *n* days.

-mtime <i>n</i>	True if the file has been modified in <i>n</i> days.
-ctime <i>n</i>	True if the file has been changed in <i>n</i> days.
-exec <i>cmd</i>	True if the executed <i>cmd</i> returns a zero value as exit status. The end of <i>cmd</i> must be punctuated by an escaped semicolon. A command argument { } is replaced by the current path name.
-ok <i>cmd</i>	Like -exec except that the generated command line is printed with a question mark first, and is executed only if the user responds by typing y.
-cpio<i>device</i>	Always true; write the current file on <i>device</i> in <i>cpio</i> (F) format (5120-byte records).
-print	Always true; causes the current path name to be printed.
-newer <i>file</i>	True if the current file has been modified more recently than the argument <i>file</i> .
(<i>expression</i>)	True if the parenthesized expression is true (parentheses are special to the shell and must be escaped).

The primaries may be combined using the following operators (in order of decreasing precedence):

negation	The negation of a primary is specified with the exclamation (!) unary <i>not</i> operator.
AND	The AND operation is implied by the juxtaposition of two primaries.
OR	The OR operation is specified with the -o operator given between two primaries.

Example

The following removes all files named **a.out** or ***.out** that have not been accessed for a week:

```
find / \( -name a.out -o -name '*.out' \) -atime +7 -exec rm {} \;
```

Files

/etc/passwd
/etc/group

See Also

cpio(C)(F), sh(C), stat(S), test(C)

Name

finger – Finds information about users.

Syntax

finger [-bfilpqsw] [login1 [login2 ...]]

Description

By default *finger* lists the login name, full name, terminal name and write status (as a "*" before the terminal name if write permission is denied), idle time, login time, office location, and phone number (if they are known) for each current XENIX user. (Idle time is minutes if it is a single integer, hours and minutes if a colon (:) is present, or days and hours if a "d" is present.)

A longer format also exists and is used by *finger* whenever a list of names is given. (Account names as well as first and last names of users are accepted.) This is a multiline format; it includes all the information described above as well as the user's home directory and login shell, any plan which the person has placed in the file *.plan* in their home directory, and the project on which they are working from the file *.project* which is also in the home directory.

finger options are:

- b Briefer long output format of users.
- f Suppresses the printing of the header line (short format).
- i Quick list of users with idle times.
- l Forces long output format.
- p Suppresses printing of the *.plan* files.
- q Quick list of users.
- s Forces short output format.
- w Forces narrow format list of specified users.

Files

/etc/utmp	Who file
/etc/passwd	User names, offices, phones, login directories, and shells

/usr/adm/lastlog	Last login times
\$HOME/.plan	Plans
\$HOME/.project	Projects

See Also

who(C)

Credit

This utility was developed at the University of California at Berkeley and is used with permission.

Notes

Only the first line of the *.project* file is printed.

Entries in the */etc/passwd* file have the following format:

login name:user password(coded):user ID:group ID:comments:home directory:login shell

The comment field corresponds to configurable columns in the *finger* output. For example, in the following */etc/passwd* entry:

blf:Tg6bLFzOwgfbA:47:5:Brian Foster, Mission, x70, 767-1234
:/u/blf:/bin/shV

the comment field, "Brian Foster, Mission, x70, 767-1234", contains data for the "In Real Life", "Office", and "Home Phone", columns of the *finger* listings.

Idle time is computed as the elapsed time since any activity on the given terminal. This includes previous invocations of *finger* which may have modified the terminal's corresponding device file */dev/tty??*.

Name

fixhdr – Changes executable binary file headers.

Syntax

fixhdr **option files**

Description

fixhdr changes the header of output files created by link editors or assemblers. The kinds of modifications include changing the format of the header, the fixed stack size, the standalone load address, and symbol names.

Using *fixhdr* allows the use of binary executable files, created under other versions or machines, by simply changing the header information so that it is usable by the target cpu.

These are the options to *fixhdr* :

- xa Change the *x.out* format of the header to the *a.out* format.
- xb Change the *x.out* format of the header to the *b.out* format.
- x4 Change the *x.out* format of the header to the 4.2BSD *a.out* format.
- x5 [-n] Change the *x.out* format of the header to 5.2 (UNIX™ System V release 2) *a.out* format. The **-n** flag causes leading underscores on symbol names to be passed with no modifications.
- ax -c [11,86] Change the *a.out* format of the header to the *x.out* format. The **-c** flag specifies the target cpu. 11 specifies a PDP-11 cpu. 86 specifies one of the 8086 family of cpus (8086, 8088, 80186, or 80286).
- bx Change the *b.out* format of the header to the *x.out* format.
- 5x [-n] Change the 5.2 (UNIX System V release 2) *a.out* format of the header to the *x.out* format. The **-n** flag causes leading underscores on symbol names to be passed with no modifications.

- 86x Add the *x.out* header format to the *86rel* object module format. See *86rel*(F).
- F *num* Add (or change) the fixed stack size specified in the *x.out* format of the header. *num* must be a hexadecimal number.
- A *num* Add (or change) the standalone load address specified in the *x.out* format of the header. *num* must be a hexadecimal number.
- M[sm]lh] Change the model of the *x.out* or *86rel* format. Model refers to the compiler model specified when creating the binary. *s* refers to small model, *m* refers to medium model, *l* refers to large model, and *h* refers to huge model.
- v [2,3,5,7] Change the version of XENIX specified in the header. XENIX version 2 was based on UNIX Version 7.
- s *s1=s2* [-s *s3=s4*] Change symbol names, where symbol name *s1* is changed to *s2*.
- r Ensure that the resolution table is of non-zero size.
- C *cpu* Set the *cpu* type. *cpu* can be 186, 286, 286, 8086, others.

Files

/usr/bin/fixhdr

See Also

a.out(F), 86rel(F)

Notes

Give *fixhdr* one option at a time. If you need to make more than one kind of modification to a file, use *fixhdr* on the original file. Then use it again on the *fixhdr* output, specifying the next option. Copy the original file if you need an unmodified version as *fixhdr* makes the modifications directly to the file.

Name

format - format floppy disks

Syntax

format [-f] [-q] [device] [-i interleave]

Description

format formats diskettes for use with XENIX. It may be used either interactively or from the command line. The default drive is */dev/rfd0*.

Options

The following command line options are available:

-f Suppresses the interactive feature. The *format* program does not wait for user-confirmation before starting to format the diskette. Regardless of whether or not you run *format* interactively, track and head information is displayed.

device

This specifies the device to be formatted. The default device is */dev/rfd0*.

-i interleave

Specifies the interleave factor.

-q

Quiet option. Suppresses the track and head output information normally displayed. Although this option does not suppress the interactive prompt, it would typically be used with **-f** to produce no output at all.

Usage

To run *format* interactively, enter:

format

followed by any of the legal options except **-f**, and press RETURN. When you run *format* interactively, you see the prompt:

insert diskette in drive and press return when ready

When you press RETURN at this prompt, *format* begins to format

the diskette.

If you specify the **-f** option, you do not see this prompt. Instead, the program begins formatting immediately upon invocation.

Unless you specify the **-q** option, *format* displays which track and head it is currently on:

track # head #

The number signs above are replaced by the actual track and head information.

Files

/dev/rfd[0 - n]

See Also

fd(M)

Notes

The *format* utility does not format floppies for use under DOS. Also, XENIX requires error free floppies.

It is not advisable to format a low density (48tpi) diskette on a high density (96tpi) floppy drive. Diskettes written on a high density drive should be read on high density drives. A low density diskette written on a high density drive may not be unreadable on a low density drive.

Name

`fsck` – Checks and repairs file systems.

Syntax

`/bin/fsck [options] [file-system] ...`

Description

`fsck` audits and interactively repairs inconsistent conditions for XENIX System V file systems. If the file system is consistent, the the number of files, number of blocks used, and number of blocks free are reported. If the file system is inconsistent, the operator is prompted for concurrence before each correction is attempted. It should be noted that most corrective actions result in some loss of data. The amount and severity of the loss may be determined from the diagnostic output. The default action for each consistency correction is to wait for the operator to respond “yes” or “no”. If the operator does not have write permission `fsck` defaults to the action of the `-n` option.

The following flags are interpreted by `fsck`:

- `-y` Assumes a yes response to all questions asked by `fsck`.
- `-n` Assumes a no response to all questions asked by `fsck`; do not open the file system for writing.
- `-sb:c` Ignores the actual free list and (unconditionally) reconstructs a new one by rewriting the super-block of the file system. The file system *must* be unmounted while this is done.

The `-sb:c` option allows for creating an optimal free-list organization. The following forms are supported:

`-s`
`-sBlocks-per-cylinder:Blocks-to-skip` (file system interleave)
(for anything else)

If `b:c` is not given, then the values used when the file system was created are used. If these values were not specified, then a reasonable default value is used.

- `-S` Conditionally reconstructs the free list. This option is like `-sb:c` above except that the free list is rebuilt only if there are no discrepancies discovered in the file system. Using `-S` forces a “no” response to all questions asked by `fsck`. This option is useful for forcing free list reorganization on uncontaminated file systems.

- t If *fsck* cannot obtain enough memory to keep its tables, it uses a scratch file. If the -t option is specified, the file named in the next argument is used as the scratch file, if needed. Without the -t flag, *fsck* prompts the operator for the name of the scratch file. The file chosen should not be on the file system being checked, and if it is not a special file or did not already exist, it is removed when *fsck* completes. If the system has a large hard disk there may not be enough space on another filesystem for the scratch file. In such cases, if the system has a floppy drive, use a blank, formatted floppy in the floppy drive with (for example) */dev/fd0* specified as the scratch file.
- q Quiet *fsck*. Do not print size-check messages in Phase 1. Unreferenced *fifo5* files will selectively be removed. If *fsck* requires it, counts in the superblock will be automatically fixed and the free list salvaged.
- D Directories are checked for bad blocks. Useful after system crashes.
- f Fast check. Check block and sizes (Phase 1) and check the free list (Phase 5). The free list will be reconstructed (Phase 6) if it is necessary.
- rr Recovers the root file system. The required *filesystem* argument must refer to the root file system, and preferably to the block device (normally */dev/root*). This switch implies -y and overrides -n . If any modifications to the file system are required, the system will be automatically shutdown to insure the integrity of the file system.
- c Causes any supported file system to be converted to the type of the current file system. The user is prompted to verify the request for each file system that requires conversion unless the -y option is specified. It is recommended that every file system be checked with this option *while unmounted* if it is to be used with the current version of XENIX. To update the active root file system, it should be checked with:

`fsck -c -rr /dev/root`

If no *file-systems* are specified, *fsck* reads a list of default file systems from the file */etc/checklist*.

Inconsistencies checked are as follows:

- Blocks claimed by more than one inode or the free list
- Blocks claimed by an inode or the free list outside the range of the file system
- Incorrect link counts
- Size checks:
 - Incorrect number of blocks
 - Directory size not 16-byte aligned
- Bad inode format
- Blocks not accounted for anywhere
- Directory checks:
 - File pointing to unallocated inode
 - Inode number out of range
- Super-block checks:
 - More than 65536 inodes
 - More blocks for inodes than there are in the file system
- Bad free block list format
- Total free block or free inode count incorrect

Orphaned files and directories (allocated but unreferenced) are, with the operator's concurrence, reconnected by placing them in the **lost+found** directory. The name assigned is the inode number. The only restriction is that the directory **lost+found** must preexist in the root of the file system being checked and must have empty slots in which entries can be made. This is accomplished by making **lost+found**, copying a number of files to the directory, and then removing them (before *fsck* is executed).

dfsck allows two file system checks on two different drives simultaneously. *Options1* and *options2* are used to pass options to *fsck* for the two sets of file systems. A - is the separator between file system groups.

Files

/etc/checklist Contains default list of file systems to check

See Also

checklist(F), filesystem(F)

Diagnostics

The diagnostics produced by *fsck* are intended to be self-explanatory.

Notes

fsck will not run on a mounted non-raw file system unless the file system is the root file system or unless the *-n* option is specified and no writing out of the file system will take place. If any such attempt is made, a warning is displayed and no further processing of the file system is done for the specified device.

Although checking a raw device is almost always faster, there is no way to tell if the file system is mounted. And cleaning a mounted file system will almost certainly result in an inconsistent superblock.

Warning

File systems created under XENIX-86 version 3.0 are not supported under XENIX System V because the word ordering in type *long* variables has changed. *fsck* is capable of auditing and repairing XENIX version 3.0 file systems if the word ordering is correct.

For the root file system, “*fsck -rr /dev/root*” should be run and for all other file systems, “*fsck /dev/??*” on the *unmounted* block device should be used.

Name

`getopt` - Parses command options.

Syntax

```
set -- `getopt optstring $*`
```

Description

getopt is used to check and break up options in command lines for parsing by shell procedures. *Optstring* is a string of recognized option letters (see *getopt*(S)). If a letter is followed by a colon, the option is expected to have an argument which may or may not be separated from it by whitespace. The special option `--` is used to delimit the end of the options. *getopt* will place `--` in the arguments at the end of the options, or recognize it if used explicitly. The shell arguments (`$1 $2 . . .`) are reset so that each option is preceded by a dash (`-`) and in its own shell argument; each option argument is also in its own shell argument.

Example

The following code fragment shows how one can process the arguments for a command that can take the options **a** and **b**, and the option **o**, which requires an argument:

```
set -- `getopt abo: $*`
if [ $? != 0 ]
then
    echo $USAGE
    exit 2
fi
for i in $*
do
    case $i in
        -a | -b)    FLAG=$i; shift;;
        -o)        OARG=$2; shift; shift;;
        -)         shift; break;;
        esac
    done
```

This code will accept any of the following as equivalent:

```
cmd -aoarg file file
cmd -a -o arg file file
cmd -oarg -a file file
cmd -a -oarg -- file file
```

See Also

sh(C), getopt(S)

Diagnostics

getopt prints an error message on the standard error when it encounters an option letter not included in *optstring*.

Notes

The “Syntax” given for this utility assumes the user has a *sh*(C) shell.

Name

grep, egrep, fgrep – Searches a file for a pattern.

Syntax

grep [-bchlnsvy] [expression] [files]

egrep [-bchlnv] [expression] [files]

fgrep [-bclnvxy] [strings] [files]

Description

Commands of the *grep* family search the input *files* (standard input default) for lines matching a pattern. Normally, each line found is copied to the standard output. *grep* patterns are limited regular *expressions* in the style of *ed*(C); it uses a compact nondeterministic algorithm. *egrep* patterns are full regular *expressions*; it uses a fast deterministic algorithm that sometimes needs exponential space. *fgrep* patterns are fixed *strings*; it is fast and compact. The following *options* are recognized:

- v** All lines but those matching are displayed.
- x** Displays only exact matches of an entire line. (*fgrep* only.)
- c** Only a count of matching lines is displayed.
- l** Only the names of files with matching lines are displayed, separated by newlines.
- h** Prevents the name of the file containing the matching line from being appended to that line. Used when searching multiple files.
- n** Each line is preceded by its relative line number in the file.
- b** Each line is preceded by the block number on which it was found. This is sometimes useful in locating disk block numbers by context.
- s** Suppresses error messages produced for nonexistent or unreadable files. (*grep* only.)
- y** Turns on matching of letters of either case in the input so that case is insignificant. Does not work for *egrep*.

-e *expression*

Same as a simple *expression* argument, but useful when the *expression* begins with a dash (-).

-f *file*

The regular *expression* for *grep* or *egrep*, or *strings* list (for *fgrep*) is taken from the *file*.

In all cases, the filename is output if there is more than one input file. Care should be taken when using the characters \$, *, [, ^, |, (,), and \ in *expression*, because they are also meaningful to the shell. It is safest to enclose the entire *expression* argument in single quotation marks.

Fgrep searches for lines that contain one of the *strings* separated by newlines.

Egrep accepts regular expressions as in *ed*(C), except for \ (and \), with the addition of the following:

- A regular expression followed by a plus sign (+) matches one or more occurrences of the regular expression.
- A regular expression followed by a question mark (?) matches 0 or 1 occurrences of the regular expression.
- Two regular expressions separated by a vertical bar (|) or by a newline match strings that are matched by either regular expression.
- A regular expression may be enclosed in parentheses () for grouping.

The order of precedence of operators is [], then * ? +, then concatenation, then the backslash (\) and the newline.

See Also

ed(C), *sed*(C), *sh*(C)

Diagnostics

Exit status is 0 if any matches are found, 1 if none, 2 for syntax errors or inaccessible files.

Notes

Ideally there should be only one *grep*, but there isn't a single algorithm that spans a wide enough range of space-time tradeoffs.

Lines are limited to 256 characters; longer lines are truncated.

Egrep does not recognize ranges, such as [a-z], in character classes.

When using *grep* with the *-y* option, the search is not made totally case insensitive in character ranges specified within brackets.

Multiple strings can be specified in *fgrep* without using a separate strings file by using the quoting conventions of the shell to imbed newlines in the *single* string argument. For example, you might enter the following on the command line:

```
fgrep 'string1
string2
string3' text.file
```

Similarly, multiple strings can be specified in *egrep* by doing:

```
egrep 'string1|string2|string3' text.file
```

Thus *egrep* can do almost anything that *grep* and *fgrep* can do.

Name

grpcheck – Checks group file.

Syntax

grpcheck [file]

Description

grpcheck verifies all entries in the group file. This verification includes a check of the number of fields, group name, group ID, and whether all login names appear in the password file. The default group file is **/etc/group**.

Files

/etc/group

/etc/passwd

See Also

pwcheck(C), **group(M)**, **passwd(M)**

Diagnostics

Group entries in **/etc/group** with no login names are flagged.

Name

haltsys – Closes out the file systems and halts the CPU.

Syntax

/etc/haltsys

Description

haltsys does a *shutdn()* system call (see *shutdn(S)*) to flush out pending disk I/O, mark the file systems clean, and halt the processor. *haltsys* takes effect immediately, so user processes should be killed beforehand. *shutdown(C)* is recommended for normal system termination, since it warns users, cleans things up, then calls *haltsys*. Use *haltsys* directly only if some system problem prevents the running of *shutdown*.

Notes

haltsys locks hard disk heads.

See Also

shutdn(S), *shutdown(C)*

Name

hd - Displays files in hexadecimal format.

Syntax

hd [**-format** [**-s** *offset*] [**-n** *count*] [*file*] ...

Description

The *hd* command displays the contents of files in hexadecimal, octal, decimal, and character formats. Control over the specification of ranges of characters is also available. The default behavior is with the following flags set: “-abx -A”. This says that addresses (file offsets) and bytes are printed in hexadecimal and that characters are also printed. If no *file* argument is given, the standard input is read.

Options include:

-s *offset* Specify the beginning offset in the file where printing is to begin. If no ‘file’ argument is given, or if a seek fails because the input is a pipe, ‘offset’ bytes are read from the input and discarded. Otherwise, a seek error will terminate processing of the current file.

The *offset* may be given in decimal, hexadecimal (preceded by ‘0x’), or octal (preceded by a ‘0’). It is optionally followed by one of the following multipliers: w, l, b, or k; for words (2 bytes), long words (4 bytes), half kilobytes (512 bytes), or kilobytes (1024 bytes). Note that this is the one case where “b” does *not* stand for bytes. Since specifying a hexadecimal offset in blocks would result in an ambiguous trailing ‘b’, any offset and multiplier may be separated by an asterisk (*).

-n *count* Specify the number of bytes to process. The *count* is in the same format as *offset*, above.

Format Flags

Format flags may specify addresses, characters, bytes, words (2 bytes) or longs (4 bytes) to be printed in hex, decimal, or octal. Two special formats may also be indicated: text or ascii. Format and base specifiers may be freely combined and repeated as desired in order to specify different bases (hexadecimal, decimal or octal) for different output formats (addresses, characters, etc.). All format flags appearing in a single argument are applied as appropriate to all other flags in that argument.

acbwIA

Output format specifiers for addresses, characters, bytes, words, longs and ascii respectively. Only one base specifier will be used for addresses; the address will appear on the first line of output that begins each new offset in the input.

The character format prints printable characters unchanged, special C escapes as defined in the language, and the remaining values in the specified base.

The ascii format prints all printable characters unchanged, and all others as a period (.). This format appears to the right of the first of other specified output formats. A base specifier has no meaning with the ascii format. If no other output format (other than addresses) is given, **bx** is assumed. If no base specifier is given, *all* of **xdo** are used.

hxdo

Output base specifiers for hexadecimal, decimal and octal. If no format specifier is given, *all* of **acbwI** are used.

- t** Print a text file, each line preceded by the address in the file. Normally, lines should be terminated by a **\n character**; but long lines will be broken up. Control characters in the range 0x00 to 0x1f are printed as '^@' to '^_'. Bytes with the high bit set are preceded by a tilde (~) and printed as if the high bit were not set. The special characters (, ~, \) are preceded by a backslash (\) to escape their special meaning. As special cases, two values are represented numerically as '\177' and '\377'. This flag will override all output format specifiers except addresses.

Name

`head` – Prints the first few lines of a stream.

Syntax

`head [-count] [file ...]`

Description

This filter prints the first *count* lines of each of the specified files. If no files are specified, *head* reads from the standard input. If no *count* is specified, then 10 lines are printed.

See Also

`tail(C)`

Credit

This utility was developed at the University of California at Berkeley and is used with permission.

Name

id – Prints user and group IDs and names.

Syntax

id

Description

Id writes a message on the standard output, giving the user and group IDs and the corresponding names of the invoking process. If the effective and real IDs do not match, both are printed.

See Also

logname(C), getuid(S)

Name

imprint – print text files on an IMAGEN printer

Syntax

imprint [*pr* options] [options] [file...]

Description

imprint calls *pr* or *cat* on the input files, and prepends a document control string for an IMAGEN printer. If no file names are given, the standard input is used. All options not listed below are regarded as options to *pr* or *cat* and are passed to it. The file is not automatically sent to the printer. The user must invoke *lp*.

The following flags are accepted:

- P Specifies that the file is text, and is printed in lineprinter mode.
- D Specifies that the file is produced for a daisy printer.
- t Specifies that the file is produced for a Tektronix 4014 printer.
- I Specifies the file is an imPress file.
- p The next argument is passed to *pr* or *cat*.
- cn Print *n* copies. This turns on pagecollation.
- h The following argument is used as the banner for *pr* and as the file name for the header page of the job. Be sure to enclose the argument in quotes if it contains spaces or other special characters.
- ln Set the page length to *n* lines. This may also set the printer's interline spacing.
- n Use *cat* rather than *pr* to print the file.
- wn Set the the line width to *n* characters. A line width of more than 80 characters is printed in landscape (132 column) mode.
- 2 Print two logical pages per physical page ("2-up").

- C Suppress pagecollation (see -c above).
- F Suppress pagereversal (which is on by default).
- J Suppress generation of the job header page.
- L Print in landscape mode, 132 columns wide.
- O Print page borders.
- R Print page rules (one every two lines).

See Also

cat(C), lp(C), pr(C), ips(C)

Diagnostics

See diagnostic messages for *pr* and *cat*.

Name

ipcrm - Removes a message queue, semaphore set or shared memory ID.

Syntax

ipcrm [options]

Description

ipcrm removes one or more specified messages, a semaphore or shared memory identifiers. The identifiers are specified by the following *options*:

- q *msqid*** removes the message queue identifier *msqid* from the system and destroys the message queue and data structure associated with it.
- m *shmid*** removes the shared memory identifier *shmid* from the system. The shared memory segment and data structure associated with it are destroyed after the last detach.
- s *semid*** removes the semaphore identifier *semid* from the system and destroys the set of semaphores and data structure associated with it.
- Q *msgkey*** removes the message queue identifier, created with key *msgkey*, from the system and destroys the message queue and data structure associated with it.
- M *shmkey*** removes the shared memory identifier, created with key *shmkey*, from the system. The shared memory segment and data structure associated with it are destroyed after the last detach.
- S *semkey*** removes the semaphore identifier, created with key *semkey*, from the system and destroys the set of semaphores and data structure associated with it.

The details of the removes are described in *msgctl(S)*, *shmctl(S)*, and *semctl(S)*. The identifiers and keys may be found by using *ipcs(C)*.

See Also

ipcs(C), *msgctl(S)*, *msgget(S)*, *msgop(S)*, *semctl(S)*, *semget(S)*, *semop(S)*, *shmctl(S)*, *shmget(S)*, *shmop(S)*

Note

ipcrm cannot be used to remove semaphores created using *creatsem(S)* or to remove shared memory created using *sdget(S)*.

Name

`ipcs` – Reports the status of inter-process communication facilities.

Syntax

`ipcs [options]`

Description

`ipcs` prints certain information about active inter-process communication facilities. Without *options*, information is printed in short format for message queues, shared memory, and semaphores that are currently active in the system. Otherwise, the information that is displayed is controlled by the following *options*:

- `-q` Print information about active message queues.
- `-m` Print information about active shared memory segments.
- `-s` Print information about active semaphores.

If any of the options `-q`, `-m`, or `-s` are specified, information about only those indicated are displayed. If none of the three options are specified, information about all three are displayed.

- `-b`
Print biggest allowable size information (maximum number of bytes in messages on queue for message queues, size of segments for shared memory, and number of semaphores in each set for semaphores). See below, for the meaning of columns in a listing.
- `-c`
Print creator's login name and group name. See below.
- `-o`
Display information on outstanding usage (number of messages on queue, total number of bytes in messages on queue, and the number of processes attached to shared memory segments).
- `-p`
Display process number information. (Process ID of last process to send a message and process ID of last process to receive a message on message queues. It displays the process ID of the creating process and the process ID of the last process to attach or detach on shared memory segments.) See below.
- `-t` Print time information. (Time of the last control operation that changed the access permissions for all facilities. Time of last *msgsnd* and last *msgrcv* on message queues, last *shmat* and last *shmdt* on shared memory, and last *semop*(S) on semaphores.) See below.
- `-a`
Use all print *options*. (This is a shorthand notation for `-b`, `-c`, `-o`, `-p`, and `-t`.)

-C corefile

Use the file *corefile* in place of */dev/kmem*.

-N namelist

The argument will be taken as the name of an alternate *namelist* (*/xenix* is the default).

The column headings and the meaning of the columns in an *ipcs* listing are given below; the letters in parentheses indicate the *options* that cause the corresponding heading to appear; **all** means that the heading always appears. Note that these *options* only determine what information is provided for each facility; they do *not* determine which facilities will be listed.

T	(all)	Type of the facility: q message queue; m shared memory segment; s semaphore.
ID	(all)	The identifier for the facility entry. Note that ID is "X" for facilities created using <i>creatsem(S)</i> or <i>sdget(S)</i> .
KEY	(all)	The key used as an argument to <i>msgget</i> , <i>semget</i> , or <i>shmget</i> to create the facility entry. (Note: The key of a shared memory segment is changed to <i>IPC_PRIVATE</i> from when the segment has been removed until all processes attached to the segment detach it.)
MODE	(all)	The facility access modes and flags: The mode consists of 11 characters that are interpreted as follows: The first two characters are: R if a process is waiting on a <i>msgrcv</i> ; S if a process is waiting on a <i>msgsnd</i> ; D if the associated shared memory segment has been removed. It will disappear when the last process attached to the segment detaches it; C if the associated shared memory segment is to be cleared when the first attach is executed; - if the corresponding special flag is not set.

The next 9 characters are interpreted as three sets of three bits each. The first set refers to the owner's permissions; the next to permissions of others in the user-group of the facility entry; and the last to all others. Within each set, the first character indicates permission to read, the second character indicates permission to write or alter the facility entry, and the last character is currently unused.

The permissions are indicated as follows:

		r	if read permission is granted;
		w	if write permission is granted;
		a	if alter permission is granted;
		-	if the indicated permission is <i>not</i> granted.
OWNER	(all)	The login name of the owner of the facility entry.	
GROUP	(all)	The group name of the group of the owner of the facility entry.	
CREATOR	(a,c)	The login name of the creator of the facility entry.	
CGROUP	(a,c)	The group name of the group of the creator of the facility entry.	
CBYTES	(a,o)	The number of bytes in messages currently outstanding on the associated message queue.	
QNUM	(a,o)	The number of messages currently outstanding on the associated message queue.	
QBYTES	(a,b)	The maximum number of bytes allowed in messages outstanding on the associated message queue.	
LSPID	(a,p)	The process ID of the last process to send a message to the associated queue.	
LRPID	(a,p)	The process ID of the last process to receive a message from the associated queue.	
STIME	(a,t)	The time the last message was sent to the associated queue.	
RTIME	(a,t)	The time the last message was received from the associated queue.	
CTIME	(a,t)	The time when the associated entry was created or changed.	
NATTCH	(a,o)	The number of processes attached to the associated shared memory segment.	
SEGSZ	(a,b)	The size of the associated shared memory segment.	
CPID	(a,p)	The process ID of the creator of the shared memory entry.	
LPID	(a,p)	The process ID of the last process to attach or detach the shared memory segment.	
ATIME	(a,t)	The time the last attach was completed to the associated shared memory segment.	
DTIME	(a,t)	The time the last detach was completed on the associated shared memory segment.	
NSEMS	(a,b)	The number of semaphores in the set associated with the semaphore entry.	
OTIME	(a,t)	The time the last semaphore operation was completed on the set associated with the semaphore entry.

creatsem(S), msgop(S), sdget(S), semop(S), shmop(S)

Notes

Things can change while *ipcs* is running; the picture it gives is only a close approximation.

Name

ips – Imagen serial sequence packet protocol handler
ipbs– Imagen parallel byte stream protocol handler

Syntax

```
/usr/lib/ips [ -D string ] [ -a file ] [ -l file ] [ -i printer ] [-oprs] [ -u  
uid] [ file ]
```

Description

ips and *ipbs* are the lowest level of Imagen-provided support software. Each handles a different form of supported communications. They present a quite similar view to higher level software, allowing that to be relatively independent of communications method.

ips sends files to Imagen printers using the sequence packet protocol (see the appropriate IMAGEN system manual for further information). This protocol provides for error detection, retransmission, status reporting, and detection of unrecoverable errors.

ipbs supports the parallel byte stream communications method, which provides for flow control but no error detection and correction.

The following information is common to all these programs.

If no file name is given, stdin is read.

The following options are recognized:

-D

The next argument is taken as a string to be prepended to the file being sent. If an unrecoverable failure occurs during transmission and the file can be resent, this string will be resent as well.

-a The next argument is taken as the name of a file in which to store printer status information.

-i The following argument is the device name of the printer.

-l The next argument is taken as the name of a file in which to store logging information.

- o Normally *ips* expects to send to stdout and does not expect to have to set port characteristics. If an explicit device name is given with the -i switch, both of these assumptions are reversed. This switch serves to toggle the assumption on the need to set up port characteristics. This switch does not apply to *ipbs* which does not set up its ports.
- r If *ips* is given an explicit file name to send, it will assume the file to be rewindable. Stdin is assumed to be not rewindable. In a manner similar to the -o switch above, this switch toggles this assumption.
- s Regardless of what other indications may have been given, use stdout as the printer.
- u*uid*
Uid is a string representing the user identification number of the person to be credited with this printing job.

See Also

imprint(C), lp(C), lpinit(C)

Notes

An interface for Imagen printers is found in the directory */usr/spool/lp/model*. The file *imagen.s* provides an interface to an Imagen printer in serial mode. The file *imagen.p* provides an interface to an Imagen printer in parallel mode.

The *lpinit* program can be used to initialize an Imagen printer in either serial or parallel mode.

When using an IMAGEN printer in parallel printer mode (using *ipbs*), you must specify the quote character as ASCII 2 and the EOF character as ASCII 4. Control characters must be "taken as is". Refer to the IMAGEN system manuals provided with the printer, for information on specifying these characters in the printer configuration.

Name

join – Joins two relations.

Syntax

join [options] file1 file2

Description

join forms, on the standard output, a join of the two relations specified by the lines of *file1* and *file2*. If *file1* is a dash (–), the standard input is used.

File1 and *file2* must be sorted in increasing ASCII collating sequence on the fields on which they are to be joined, normally the first in each line.

There is one line in the output for each pair of lines in *file1* and *file2* that have identical join fields. The output line normally consists of the common field, then the rest of the line from *file1*, then the rest of the line from *file2*.

Fields are normally separated by blank, tab or newline. In this case, multiple separators count as one, and leading separators are discarded.

These options are recognized:

- an** In addition to the normal output, produces a line for each unpairable line in file *n*, where *n* is 1 or 2.
- e s** Replaces empty output fields by string *s*.
- jn m** Joins on the *m*th field of file *n*. If *n* is missing, uses the *m*th field in each file.
- o list** Each output line comprises the fields specified in *list*, each element of which has the form *n.m*, where *n* is a file number and *m* is a field number.
- tc** Uses character *c* as a separator (tab character). Every appearance of *c* in a line is significant.

JOIN (C)

JOIN (C)

See Also

awk(C), *comm*(C), *sort*(C)

Notes

With default field separation, the collating sequence is that of *sort* -b. With -t, the sequence is that of a plain sort.

Name

kill – Terminates a process.

Syntax

kill [-signo] processid ...

Description

kill sends signal 15 (terminate) to the specified processes. This will normally kill processes that do not catch or ignore the signal. The process number of each asynchronous process started with **&** is reported by the shell (unless more than one process is started in a pipeline, in which case the number of the last process in the pipeline is reported). Process numbers can also be found by using *ps*(C).

For example, if process number 0 is specified, all processes in the process group are signaled.

The killed process must belong to the current user unless he is the super-user.

If a signal number preceded by **-** is given as the first argument, that signal is sent instead of the terminate signal (see *signal*(S)). In particular “kill -9 . . .” is a sure kill.

See Also

ps(C), *sh*(C), *kill*(S), *signal*(S)

Name

l - Lists information about contents of directory.

Syntax

l [**-ACFRabcdfgilnopqrstu**] name ...

Description

For each directory argument, *l* lists the contents of the directory; for each file argument, *l* repeats its name and other requested information. The output is sorted alphabetically by default. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments appear before directories and their contents. Information is listed in the format of the “ls -l” command, which is identical to the *l* command. This format and all provided switches are described in *ls(C)* and *lc(C)*, to which should you should refer for a complete discussion of the capabilities of *l*.

Files

/etc/passwd	Contains user IDs
/etc/group	Contains group IDs

Notes

Newline and tab are considered printing characters in filenames.

The output device is assumed to be 80 columns wide.

Name

lc - Lists directory contents in columns.

Syntax

lc [-1ACFRabcdfgilmnopqrstux] *name* ...

Description

lc lists the contents of files and directories, in columns. If *name* is a directory name, lc lists the contents of the directory; if *name* is a filename, lc repeats the filename and any other information requested. Output is given in columns and sorted alphabetically. If no argument is given, the current directory is listed. If several arguments are given, they are sorted alphabetically, but file arguments appear before directories.

Files that are not the contents of a directory being interpreted are always sorted across the page rather than down the page in columns. A stream output format is available in which files are listed across the page, separated by commas. The -m option enables this format.

The options are:

- 1
Forces an output format with one entry per line.
- A
If not the root directory, this option displays all files that begin with "." (except "." and ".." themselves). Otherwise, files are displayed normally.
- C
Forces columnar output, even if redirected to a file.
- F
Causes directories to be marked with a trailing "/" and executable files to be marked with a trailing "*".
- R
Recursively lists subdirectories.
- a
Lists all entries; "." and ".." are not suppressed.
- b
Forces printing of nongraphic characters in the \ddd notation, in octal.

- c**
Sorts by time of file creation.
- d**
If the argument is a directory, lists only its name, not its contents (mostly used with **-l** to get status on directory).
- f** Forces each argument to be interpreted as a directory and lists the name found in each slot. This option turns off **-l**, **-t**, **-s**, and **-r**, and turns on **-a**; the order is the order in which entries appear in the directory.
- g**
The same as **-l**, except that the owner is not printed.
- i** Prints inode number in first column of the report for each file listed.
- l** Lists in long format, giving mode, number of links, owner, group, size in bytes, and time of last modification for each file. If the file is a special file, the size field instead contains the major and minor device numbers.
- m**
Forces stream output format.
- n**
Same as the **-l** switch, but the owner's user ID appears instead of the owner's name. If used in conjunction with the **-g** switch, the owner's group ID appears instead of the group name.
- o**
The same as **-l**, except that the group is not printed.
- p**
Pad output with spaces.
- q**
Forces printing of nongraphic characters in filenames as the character "?".
- r**
Reverses the order of sort to get reverse alphabetic or oldest first as appropriate.
- s**
Gives size in 512-byte blocks, including indirect blocks for each entry.

-t Sorts by time modified (latest first) instead of by name, as is normal.

-u
Uses time of last access instead of last modification for sorting (**-t**) or printing (**-l**).

-x
Forces columnar printing to be sorted across rather than down the page.

The following are alternate invocations of the **lc** command:

lf Produces the same output as **lc -F**.

lr Produces the same output as **lc -R**.

lx Produces the same output as **lc -x**.

The mode printed under the **-l** option contains 11 characters. The first character is:

- If the entry is a plain file
- d** If the entry is a directory
- b** If the entry is a block-type special file
- c** If the entry is a character-type special file
- p** If the entry is a named pipe
- s** If the entry is a semaphore
- m** If the entry is shared data (memory)

The next 9 characters are interpreted as 3 sets of 3 bits each. The first set refers to owner permissions; the next to permissions to others in the same user-group; and the last to all others. Within each set, the 3 characters indicate permission respectively to read, to write, or to execute the file as a program. For a directory, "execute" permission is interpreted to mean permission to search the directory for a specified file. The permissions are indicated as follows:

- r** If the file is readable
- w** If the file is writable
- x** If the file is executable

- If the indicated permission is not granted

The group-execute permission character is given as *s* if the file has set-group-ID mode; likewise the user-execute permission character is given as *s* if the file has set-user-ID mode.

The last character of the mode (normally “*x*” or “*-*”) is *t* if the 1000 bit of the mode is on. See *chmod*(C) for the meaning of this mode.

When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks, is displayed.

Files

/etc/passwd	To get user IDs for “ <i>lc -o</i> ”
/etc/group	To get group IDs for “ <i>lc -g</i> ”

Credit

This utility was developed at the University of California at Berkeley and is used with permission.

Notes

Newline and tab are considered printing characters in filenames. The output device is assumed to be 80 columns wide. Column width choices are poor for terminals that can tab.

This utility reports sizes in 512 byte blocks. On systems which use 1024 byte blocks, this means a file of 500 bytes uses 2 blocks. *lc -s* will report 2 blocks used, rather than 1 block, since the file uses one system block of 1024 bytes. Refer to the *machine*(M) manual page for the block size used by your system.

Name

line – Reads one line.

Syntax

line

Description

line copies one line (up to a newline) from the standard input and writes it on the standard output. It returns an exit code of 1 on end-of-file and always prints at least a newline. It is often used within shell files to read from the user's terminal.

See Also

gets(CP), *sh*(C)

Name

ln - Makes a link to a file.

Syntax

```
ln file1 file2
ln file1 ... directory
```

Description

A link is a directory entry referring to a file; the same file (together with its size, all its protection information, etc). may have several links to it. There is no way to distinguish a link to a file from its original directory entry. Any changes to the file are effective independent of the name by which the file is known.

In the first case, *ln* creates a link to the existing file, *file1*. The *file2* argument is a new name referring to the same file contents as *file1*.

In the second case, *directory* is the location of a directory into which one or more links are created with corresponding file names.

You cannot link to a directory or link across file systems.

See Also

cp(C), mv(C), rm(C)

Name

logname – Gets login name.

Syntax

logname

Description

logname returns the value of *getlogin(S)* or *getuid(S)* which is set when a user logs into the system.

See Also

env(C), getlogin(S), getuid(S), login(M), logname(S)

Name

lp, *lpr*, *cancel* – Send/cancel requests to lineprinter.

Syntax

```
lp [options...][name...]
or
lpr [options...][name...]
cancel [request ID s] [printers]
```

Description

lp causes the named files and associated information (collectively called a “request”) to be printed by a lineprinter. *lp* and *lpr* are equivalent commands and may be used interchangeably. If no file names are mentioned, the standard input is assumed. The file name - stands for the standard input and may be supplied on the command line in conjunction with named *files*. The order in which *files* appear is the same order in which they will be printed.

lp associates a unique request ID with each request and prints it on the standard output. This request ID can be used later to *cancel* (see *cancel*) or find the status of the request (see *lpstat(C)*).

The following options to *lp* may appear in any order and may be intermixed with file names:

- c Makes copies of the *files* to be printed immediately when *lp* is invoked. Normally, *files* will not be copied, but will be linked whenever possible. If the -c option is not given, then the user should be careful not to remove any of the *files* before the request has been printed in its entirety; any changes made to the named *files* after the request is made but before it is printed will be reflected in the printed output.
- ddest Chooses *dest* as the printer or class of printers to do the printing. If *dest* is a printer, then the request will be printed only on that specific printer. If *dest* is a class of printers, then the request will be printed on the first available printer that is a member of the class. Under certain conditions (for example, printer unavailability or file space limitation), requests for specific destinations may not be accepted (see *accept(C)* and *lpstat(C)*). By default, *dest* is taken from the environment variable LPDEST (if it is set). Otherwise, a default destination (if one exists) for the computer system is used. Destination names vary between systems (see *lpstat(C)*).

- m Sends mail (see *mail(C)*) after the files have been printed. By default, no mail is sent upon normal completion of the print request.
- nnumber Prints *number* of copies of the output. The default is one.
- ooption Specifies printer-dependent or class-dependent *options*. Several such *options* may be collected by specifying the -o keyletter more than once. For more information about what is valid for *options*, see *lpadmin(C)*.
- r Removes file after sending it.
- s Suppresses messages from *lp(C)* such as "request id is ...".
- ttitle Prints *title* on the banner page of the output.
- w Writes a message on the user's terminal after the *files* have been printed. If the user is not logged in, then mail is sent instead.

The file */etc/default/lpd* contains the setting of the variable BANNERS, whose value is the number of pages printed as a banner identifying each printout. This is normally set to either 1 or 2.

Cancel cancels line printer requests that were made by the *lp(C)* command. The command line arguments may be either request IDs (as returned by *lp(C)*) or *printer* names (for a complete list, use *lpstat(C)*). Specifying a request ID cancels the associated request even if it is currently printing. Specifying a *printer* cancels the request which is currently printing on that printer. In either case, the cancellation of a request that is currently printing frees the printer to print its next available request. User's identification and accounting data spool area contains BANNERS setting.

Files

/etc/passwd
*/usr/spool/lp/**
/etc/default/lpd

See Also

enable(C), *lpstat(C)*, *mail(C)*, *accept(C)*, *lpadmin(C)*, *lpsched(C)*

Name

lpadmin – Configures the lineprinter spooling system.

Syntax

```
/usr/lib/lpadmin -p printer [ options... ]
/usr/lib/lpadmin -x dest
/usr/lib/lpadmin -d[dest]
```

Description

lpadmin configures the lineprinter spooling system to describe printers, classes, and devices. It is used to add and remove destinations, change membership in classes, change devices for printers, change printer interface programs, and to change the system default destination. System managers may also use *lpinit*(C) to add new printing destinations to the system. *lpadmin* may not be used when the lineprinter scheduler, *lpsched*(C), is running, except where noted below.

Exactly one of the **-p**, **-d**, or **-x** options must be present for every legal invocation of *lpadmin*.

- d[dest]** Makes *dest*, an existing destination, the new system default destination. If *dest* is not supplied, then there is no system default destination. This option may be used when *lpsched*(C) is running. No other *options* are allowed with **-d**.
- xdest** Removes destination *dest* from the LP system. If *dest* is a printer and is the only member of a class, then the class will be deleted, too. No other *options* are allowed with **-x**.
- pprinter** Names a *printer* to which all of the *options* below refer. If *printer* does not exist then it will be created.

The following *options* are only useful with **-p** and may appear in any order. For ease of discussion, the printer will be referred to as *p* below.

- cclass** Inserts printer *p* into the specified *class*. *Class* will be created if it does not already exist.
- eprinter** Copies an existing *printer*'s interface program to be the new interface program for *p*.

- h** Indicates that the device associated with *p* is hardwired. This *option* is assumed when creating a new printer unless the **-l** *option* is supplied.
- iinterface** Establishes a new interface program for *p*. *Interface* is the pathname of the new program.
- l** Indicates that the device associated with *p* is a login terminal. The lineprinter scheduler, *lpsched*(C), disables all login terminals automatically each time it is started. Before re-enabling *p*, its current *device* should be established using *lpadmin*.
- mmodel** The model printer interface program, *dumb*, is supplied with XENIX lineprinter software. It is a shell procedure which interfaces *lpsched*(C) and print devices. It can be found in the directory */usr/spool/lp/model* and may be used as is with *lpadmin -m* or *lpinit*(C). This program is an interface for a line printer without special functions and protocol. Form feeds are assumed. System managers may modify copies of *dumb* and then use *lpadmin -i* to associate the copies with printers.
- rclass** Removes printer *p* from the specified *class*. If *p* is the last member of the *class*, then the *class* will be removed.
- vdevice** Associates a new *device* with printer *p*. *Device* is the pathname of a file that is writable by the system manager, *lp*. Note that there is nothing to stop a system manager from associating the same *device* with more than one *printer*. If only the **-p** and **-v** *options* are supplied, then *lpadmin* may be used while the scheduler is running.

Restrictions

When creating a new printer, the **-v** option and one of the **-e**, **-i**, or **-m** options must be supplied. Only one of the **-e**, **-i**, or **-m** options may be supplied. The **-h** and **-l** keyletters are mutually exclusive. Printer and class names may be no longer than 14 characters and must consist entirely of the characters A - Z , a - z , 0 - 9 and _ (underscore).

Models

Model printer interface programs are shell procedures which interface between *lpsched*(C) and devices. Models reside in the directory */usr/spool/lp/model* and may be used as is with *lpadmin -m*.

Models should have 644 permission if owned by *lp* & bin, or 664 permission if owned by bin & bin. System managers may modify copies of models and then use *lpadmin -i* to associate them with printers. If printers have special options, these can be included in the interface program. Users can then choose an option with the *lp -o* command.

One model interface program is supplied with XENIX lineprinter software: *dumb*. This is an interface program for a lineprinter without special functions and protocol. Form feeds are assumed. This is a good model for system managers to copy and modify.

Serial printers that need delays or other special *stty*(C) options (such as mapping CR to newline) should have this string included in the model interface program:

```
stty [ options ... ] 0<&1
```

Files

```
/usr/spool/lp/*
```

See Also

accept(C), *enable*(C), *lp*(C), *lpinit*(C), *lpsched*(C), *lpstat*(C)

Name

lpinit – Adds new lineprinters to system.

Syntax

/etc/lpinit

Description

lpinit is a shell script for configuring and adding new lineprinters to a system. It should only be executed by the system manager. *lpinit* asks a series of questions for which the default answers are displayed. The system manager can enter a response or press the RETURN key for the default answer. If the system manager enters H in response to the first question, a help message is displayed. *lpinit* prompts users for the following information:

- The print device pathname (default is */dev/lp*).
- The name of the printer (default is *linepr*).
- The pathname of the printer interface program (default is */usr/spool/lp/model/dumb*).

The printer name can be any combination of up to 14 alphanumeric characters or underscores. A printer interface program can be a shell script, C program, or any executable program; or the model interface program, */usr/spool/lp/model/dumb*, can be copied and modified. (See the section “Models” on the manual page *lpadmin*(C).)

After the system manager has responded to these questions, */etc/lpinit* stops the print scheduler *lp sched*, changes the acceptance status of the new lineprinter to “accept,” and enables it to print files. */etc/lpinit* then asks if the new printer will be the default printing destination (default is yes). All nonspecific print requests are routed to the default destination (see *lp*(C)).

The steps to configure a new printer can be taken separately, (see *lpadmin*(C), *accept*(C), *enable*(C), and *lp sched*(C) for more information).

Files

/etc/lpinit

See Also

accept(C), enable(C), lp(C), lpadmin(C), lpsched(C)

Name

lpsched, *lpshut*, *lpmove* – Starts/stops the lineprinter request scheduler and moves requests.

Syntax

```
/usr/lib/lpsched  
/usr/lib/lpshut  
/usr/lib/lpmove requests destinations  
/usr/lib/lpmove dest1 dest2
```

Description

lpsched schedules requests taken by *lp(C)* for printing on lineprinters.

lpshut shuts down the lineprinter scheduler. All printers that are printing at the time *lpshut* is invoked will stop printing. Requests that were printing at the time a printer was shut down will be reprinted in their entirety after *lpsched* is started again. All lineprinter commands perform their functions even when *lpsched* is not running.

lpmove moves requests that were queued by *lp(C)* between lineprinter destinations. This command may be used only when *lpsched* is not running. The first form of the command moves the named *requests* to the lineprinter *destinations*, *dest*. *Requests* are request IDs as returned by *lp(C)*. The second form moves all requests for destination *dest1* to destination *dest2*. As a side effect, *lp(C)* will reject requests for *dest1*.

Note that *lpmove* never checks the acceptance status for the new destination when moving requests (see *accept(C)*).

Files

```
/usr/spool/lp/*
```

accept(C), *enable(C)*, *lp(C)*, *lpadmin(C)*, *lpinit(C)*, *lpstat(C)*

Name

lpstat – prints lineprinter status information

Syntax

lpstat [options ...]

Description

lpstat prints information about the current status of the lineprinter system.

If no *options* are given, then *lpstat* prints the status of all requests made to *lp*(C) by the user. Any arguments that are not *options* are assumed to be request IDs (as returned by *lp*). *lpstat* prints the status of these requests. *Options* may appear in any order and may be repeated and intermixed with other arguments. Some of the following options may be followed by *list* which can be in one of two forms: a list of items separated from one another by a comma, or a list of items enclosed in double quotes and separated from one another by a comma and/or one or more spaces. For example:

-u“user1, user2, user3”

The omission of a *list* following such options causes all information relevant to the option to be printed, for example:

lpstat -o

prints the status of all output requests.

- a[*list*] Prints acceptance status (with respect to *lp*) of destinations for requests. *List* is a list of intermixed printer names and class names.
- c[*list*] Prints class names and their members. *List* is a list of class names.
- d Prints the system default destination for *lp*.
- o[*list*] Prints the status of output requests. *List* is a list of intermixed printer names, class names, and request IDs.
- p[*list*] Prints the status of printers. *List* is a list of printer names.
- r Prints the status of the lineprinter scheduler, *lpsched*.

- s Prints a status summary, including the status of the line-printer scheduler, the system default destination, a list of class names and their members, and a list of printers and their associated devices.
- t Prints all status information.
- u[*list*] Prints status of output requests for users. *List* is a list of login names.
- v[*list*] Prints the names of printers and the pathnames of the devices associated with them. *List* is a list of printer names.

Files

/usr/spool/lp/*

See Also

enable(C), lp(C)

Name

ls - Gives information about contents of directories.

Syntax

ls [-ACFRabcdfgilmnopqrstux] [names]

Description

For each directory named, *ls* lists the contents of that directory; for each file named, *ls* repeats its name and any other information requested. By default, the output is sorted alphabetically. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments are processed before directories and their contents.

There are three major listing formats. The default format is to list one entry per line, the **-C** and **-x** options enable multi-column formats, and the **-m** option enables stream output format in which files are listed across the page, separated by commas. In order to determine output format for the **-C**, **-x**, and **-m** options, *ls* uses an environment variable, **COLUMNS**, to determine the number of character positions available on one output line. If this variable is not set, the *termcap* database is used to determine the number of columns, based on the environment variable **TERM**. If this information cannot be obtained, 80 columns are assumed.

There are many options:

- A List all entries; entries whose name begin with a period (.) are listed. Does not list current directory (.) and directory above (..).
- a Lists all entries; entries whose name begin with a period (.) are listed.
- R Recursively lists subdirectories encountered.
- d If an argument is a directory, lists only its name (not its contents); often used with **-l** to get the status of a directory.
- C Multi-column output with entries sorted down the columns.
- x Multi-column output with entries sorted across rather than down the page.

- m Stream output format.
- l Lists in long format, giving mode, number of links, owner, group, size in bytes, and time of last modification for each file (see below). If the file is a special file, the size field will contain the major and minor device numbers, rather than a size.
- n The same as -l, except that the owner's UID and group's GID numbers are printed, rather than the associated character strings.
- o The same as -l, except that the group is not printed.
- g The same as -l, except that the owner is not printed.
- r Reverses the order of sort to get reverse alphabetic or oldest first, as appropriate.
- t Sorts by time modified (latest first) instead of by name.
- u Uses time of last access instead of last modification for sorting use with the -t option.
- c Uses time of last modification of the inode (file created, mode changed, etc.) for sorting use with -t option.
- p Puts a slash (/) after each filename if that file is a directory.
- F Puts a slash (/) after each filename if that file is a directory and puts an asterisk (*) after each filename if that file is executable.
- b Forces printing of non-graphic characters to be in the octal \ddd notation.
- q Forces printing of non-graphic characters in file names as the character (?).
- i For each file, prints the inode number in the first column of the report.
- s Gives size in blocks, including indirect blocks, for each entry.
- f Forces each argument to be interpreted as a directory and lists the name found in each slot. This option turns off -l, -t, -s, and -r, and turns on -a; the order is the order in which entries appear in the directory.

The mode printed under the -l option consists of 11 characters. The first character is:

- If the entry is an ordinary file.
- d** If the entry is a directory.
- b** If the entry is a block special file.
- c** If the entry is a character special file.
- p** If the entry is a named pipe.
- s** If the entry is a semaphore.
- m** If the entry is a shared data (memory) file.

The next 9 characters are interpreted as 3 sets of 3 bits each. The first set refers to the owner's permissions; the next to permissions of others in the user-group of the file; and the last to all others. Within each set, the 3 characters indicate permission to read, to write, and to execute the file as a program, respectively. For a directory, "execute" permission is interpreted to mean permission to search the directory for a specified file.

The permissions are indicated as follows:

- r** If the file is readable.
- w** If the file is writable.
- x** If the file is executable.
- If the indicated permission is *not* granted.

The group-execute permission character is given as **s** if the file has set-group-ID mode; likewise, the user-execute permission character is given as **S** if the file has set-user-ID mode. The last character of the mode (normally **x** or **-**) is **t** if the 1000 (octal) bit of the mode is on; see *chmod*(C) for the meaning of this mode. The indications of set-ID and 1000 bit of the mode are capitalized if the corresponding execute permission is *not* set.

When the sizes of the files in a directory are listed, a total count of blocks including indirect blocks is printed.

Files

- | | |
|-------------|--|
| /etc/passwd | Gets user IDs for <code>ls -l</code> and <code>ls -o</code> |
| /etc/group | Gets group IDs for <code>ls -l</code> and <code>ls -g</code> |

/etc/termcap/* Gets terminal information

See Also

chmod(C), find(C), l(C), lc(C), termcap(C)

Notes

Newline and tab are considered printing characters in filenames.

Unprintable characters in filenames may confuse the columnar output options.

This utility reports sizes in 512 byte blocks. Systems which define a block as 1024 characters, "round-off" the size of files containing 511 or fewer bytes to 1 block. *ls -s* interprets 1 block from a 1024 byte block system as 2 of its own 512 byte blocks. Thus a 500 byte file is interpreted as 2 blocks rather than 1. Refer to the **machine(M)** manual page for the block size used by your system.

Name

mail – Sends, reads or disposes of mail.

Syntax

mail **[-u user] [-f mailbox] [-e] [-R] [-i] [users ...]**

mail **[-s subject] [-i] [user ...]**

Description

mail is a mail processing system that supports composing of messages, and sending and receiving of mail between multiple users. When sending mail, a *user* is the name of a user or of an alias assigned to a machine or to a group of users.

Options include:

-u user

Tells *mail* to read the system mailbox belonging to the specified *user*.

-f mailbox

Tells *mail* to read the specified *mailbox* instead of the default user's system mailbox.

-e Allows escapes from compose mode when input comes from a file.

-R

Makes the mail session “read-only” by preventing alteration of the mailbox being read. Useful when accessing system-wide mailboxes.

-i Tells *mail* to ignore interrupts sent from the terminal. This is useful when reading or sending mail over telephone lines where “noise” may produce unwanted interrupts.

-s subject

Specifies *subject* as the text of the *Subject:* field for the message being sent.

Sending mail

To send a message to one or more other people, invoke *mail* with arguments which are the names of people to send to. You are then expected to type in your message, followed by a Ctrl-D at the beginning of a line.

Reading Mail

To read mail, invoke *mail* with no arguments. This will check your mail out of the system-wide directory so that you can read and dispose of the messages sent to you. A message header is printed out for each message in your mailbox. The current message is initially the last numbered message and can be printed using the **print** command (which can be abbreviated **p**). You can move among the messages much as you move between lines in *ed*, with the commands **+** and **-** moving backwards and forwards, and simple numbers typing the addressed message.

If new mail arrives during the mail session, you can read in the new messages with the **restart** command.

Disposing of Mail

After examining a message, you can **delete** (**d**) the message or **reply** (**r**) to it. Deletion causes the *mail* program to forget about the message. This is not irreversible, the message can be **undeleted** (**u**) by giving its number, or the *mail* session can be aborted by giving the **exit** (**x**) command. Deleted messages will, however, disappear.

Specifying Messages

Commands such as **print** and **delete** often can be given a list of message numbers as arguments to apply to a number of messages at once. Thus "delete 1 2" deletes messages 1 and 2, while "delete 1-5" deletes messages 1 through 5. The special name "*" addresses all messages, and "\$" addresses the last message; thus the command **top** which prints the first few lines of a message could be used in "top *" to print the first few lines of all messages.

Replying to or Originating Mail

You can use the **reply** command to set up a response to a message, sending it back to the person who sent it. Then you can enter in the text of the reply, and press Ctrl-D to send it. While you are composing a message, *mail* treats lines beginning with a tilde (~) as special. For instance, typing "~m" alone on a line, places a copy of the current message into the response, right shifting it by one tabstop. Other escapes set up subject fields, add and delete recipients to the message, and allow you to escape to an editor to revise the message or to a shell to run some commands. (These options are given in the summary below.)

Ending a Mail Session

You can end a *mail* session with the **quit (q)** command. Messages that have been examined go to your *mbox* file unless they have been deleted, in which case they are discarded. Unexamined messages go back to the post office. The **-f** option causes *mail* to read in the contents of your *mbox* (or the specified file) for processing; when you **quit**, *mail* writes undeleted messages back to this file. The **-i** option causes *mail* to ignore interrupts.

Using Aliases and Distribution Lists

It is also possible to create a personal distribution list. For instance, you can send mail to "cohorts" and have it go to a group of people. Such lists can be defined by placing a line like

```
alias cohorts bill bob barry bobo betty beth bobbi
```

in the file *.mailrc* in your home directory. The current list of such aliases can be displayed by the **alias (a)** command in *mail*. System-wide distribution lists can be created by editing */usr/lib/mail/aliases*, see *aliases(M)*; these are kept in a slightly different syntax. In *mail* you send, personal aliases will be expanded in mail sent to others so that they will be able to **reply** to the recipients. System-wide *aliases* are not expanded when the mail is sent, but any reply returned to the machine will have the system-wide alias expanded.

mail has a number of options which can be set in the *.mailrc* file to alter its behavior; thus "set askcc" enables the "askcc" feature. (These options are summarized below.)

Summary

Each mail command is entered on a line by itself, and may take arguments following the command word. The command need not be entered in its entirety; the first command which matches the typed prefix is used. For the commands that take message lists as arguments; if no message list is given, then the next message forward that satisfies the command's requirements is used. If there are no messages forward of the current message, the search proceeds backwards, and if there are no messages at all, *mail* types "No applicable messages" and aborts the command.

- Goes to the previous message and prints it out. If given a numeric argument *n*, goes to the *n*th previous message and prints it.

+	Goes to the next message and prints it out. If given a numeric argument <i>n</i> , goes to the <i>n</i> th next message and prints it.
RETURN	Goes to the next message and prints it out.
?	Prints a brief summary of commands.
!	Executes the shell command which follows.
=	Prints out the current message number.
^	Prints out the first message.
\$	Prints out the last message.
alias	(a) With no arguments, prints out all currently-defined aliases. With one argument, prints out that alias. With more than one argument, adds the users named in the second and later arguments to the alias named in the first argument.
Alias users	Prints system-wide list of aliases for users. At least one user must be specified.
cd	(c) Changes the user's working directory to that specified, if given. If no directory is given, then changes to the user's login directory.
delete	(d) Takes a list of messages as an argument and marks them all as deleted. Deleted messages are not retained in the system mailbox after a quit, nor are they available to any command other than the <i>undelete</i> command.
dp	Deletes the current message and prints the next message. If there is no next message, <i>mail</i> says "no more messages."
echo path	Expands shell metacharacters.
edit	(e) Takes a list of messages and points the text editor at each one in turn. On return from the editor, the message is read back in.
exit	(x) Effects an immediate return to the shell without modifying the user's system mailbox, his <i>mbox</i> file, or his edit file in <i>-f</i> .
file	(fi) Prints the name of the file mail is reading. If it is a mailbox, the name of the owner is returned.

forward	(f) Forwards the current message to the named users. Current message is indented within forwarded message.
Forward	(F) Forwards the current message to the named users. Current message is <i>not</i> indented within forwarded message.
headers	(h) Lists the current range of headers, which is an 18 message group. If a "+" argument is given, then the next 18 message group is printed, and if a "-" argument is given, the previous 18 message group is printed. Both "+" and "-" may take a number to view a particular window. If a message-list is given, it prints the specified headers.
hold	(ho) Takes a message list and marks each message therein to be saved in the user's system mailbox instead of in <i>mbox</i> . Use only when the switch <i>autombox</i> is set. Does not override the <i>delete</i> command.
list	Prints list of mail commands.
lpr	(l) Prints out each message in a message-list on the lineprinter.
mail	(m) Takes as arguments login names and distribution group names and sends mail to those people.
mbox	(mb) Marks messages in a message list so that they are saved in the user mailbox after leaving mail.
move <i>mesg-list mesg-num</i>	Places the messages specified in <i>mesg-list</i> after the message specified in <i>mesg-num</i> . If <i>mesg-num</i> is 0, <i>mesg-list</i> moves to the top of the mailbox.
next	(n like + or RETURN) Goes to the next message in sequence and prints it. With an argument list, types the next matching message.
print	(p) Prints out each message in a message-list on the terminal display.
quit	(q) Terminates the session, retaining all undeleted, unsaved messages in the system mailbox and removing all other messages. Files marked with a star (*) are saved; files marked with an "M" are saved in the user mailbox. If new mail has arrived during the session, the message "You have new mail" is given. If given while editing a mailbox file with the -f flag, then the mailbox file is rewritten. The user returns to the shell,

unless the rewrite of the mailbox file fails, in which case the user can escape with the `exit` command.

- reply** (r) Takes a message list and sends mail to each message author. The default message must not be deleted.
- Reply** (R) Takes a message list and sends mail to each message author *and each member of the message* just like the `mail` command. The default message must not be deleted.
- restart** Reads in messages that arrived during the current mail session.
- save** (s) Takes a message list and a filename and appends each message in turn to the end of the file. The filename, in quotation marks, followed by the line count and character count is echoed on the user's terminal.
- set** (se) With no arguments, prints all variable values. Otherwise, sets option. Arguments are of the form "option=value" or "option".
- shell** (sh) Invokes an interactive version of the shell.
- size** (si) Takes a message list and prints out the size in characters of each message.
- source** (so) Reads mail commands from the file given as its only argument.
- string** *string mesg-list*
Searches for *string* in *mesg-list*. If no *mesg-list* is specified, all undeleted messages are searched. Case is ignored in search.
- top** (t) Takes a message list and prints the top few lines of each. The number of lines printed is controlled by the variable `toplines` and defaults to six.
- undelete** (u) Takes a message list and marks each one as *not* being deleted.
- unset** (uns) Takes a list of option names and discards their remembered values; the inverse of `set`.
- visual** (v) Takes a message list and invokes `vi` on each message.

whois Looks up a list of target mail recipients and prints the real names or descriptions of each recipient. If the first character of the first argument is alphabetic, the arguments are looked up without change. Otherwise, the arguments are assumed to be a message list, in the format specified in the *Mail User's Guide*. For each message in the list, the "From" person is extracted from the header and added to the list of users to be searched.

If a target mail recipient contains a machine and user name, nothing is printed. If it is a private alias, "private alias" is printed. If it is a global alias, the name or description of the recipient is printed (contents of the \$n field in the alias file). If all of the above fail, the user is looked up in /etc/passwd; if the user is a local user, "local user" is printed. Finally, if none of the above tests and searches succeed, "unknown" is printed.

write filename

(w) Saves the body of the message in the named file.

Here is a summary of the compose escapes, which are used when composing messages to perform special functions. Compose escapes are only recognized at the beginning of lines.

~string Inserts the string of text in the message prefaced by a single tilde (~). If you have changed the escape character, then you should double that character instead.

~? Prints out help for compose escapes.

~. Same as Ctrl-D on a new line.

~!cmd Executes the indicated shell command, then returns to the message.

~|cmd Pipes the message through the command as a filter. If the command gives no output or terminates abnormally, retains the original text of the message.

~_ mail-command

Executes a mail command, then returns to compose mode.

~: mail-command

Executes a mail command, then returns to compose mode.

- ~alias** Prints list of private aliases
- ~alias *aliasname***
Prints names included in private *aliasname*.
- ~Alias** Performs aliasing by first examining private aliases and then system-wide aliases using all three global alias files (*aliases.hash*, *faliases*, and *maliases*). Only the final result is printed (non-local mail recipients will have the complete delivery path printed). The user list is taken from header fields.
- ~Alias *users*** Performs aliasing by first examining private aliases and then system-wide aliases using all three global alias files (*aliases.hash*, *faliases*, and *maliases*). Only the final result is printed (non-local mail recipients will have the complete delivery path printed). At least one user must be specified.
- ~b *name* ...** Adds the given names to the list of blind carbon copy recipients.
- ~c *name* ...** Adds the given names to the list of carbon copy recipients.
- ~cc *name* ...** Same as ~c above.
- ~d** Reads the file *dead.letter* from your home directory into the message.
- ~e** Invokes the text editor on the message collected so far. After the editing session is finished, you may continue appending text to the message.
- ~h** Edits the message header fields by typing each one in turn and allowing the user to append text to the end or modify the field with the current terminal erase and kill characters.
- ~m *mesg-list*** Reads the named messages into the message buffer, shifted right one tab. If no messages are specified, reads the current message.
- ~M *mesg-list*** Reads the named messages into the message buffer, with no indentation. If no messages are specified, reads the current message.
- ~p** Prints out the messages collected so far, prefaced by the message header fields.

- ~Print** Prints the real names or descriptions (in parentheses) after each recipient in a header field.
- ~q** Aborts the message being sent, copying the message to *dead.letter* in your home directory if *save* is set.
- ~r filename** Reads the named file into the message buffer.
- ~Return name** Adds the given names to the Return-receipt-to field.
- ~s string** Causes the named string to become the current subject field.
- ~t name ...** Adds the given names to the direct recipient list.
- ~v** Invokes a visual editor (defined by the VISUAL option) on the message buffer. After you quit the editor, you may resume appending text to the end of your message.
- ~w filename** Writes the body of the message to the named file.

Options are controlled with the **set** and **unset** commands. An option may be either a switch, in which case it is either on or off, or a string, in which case the actual value is of interest. The switch options include the following:

- askcc** Causes you to be prompted for additional carbon copy recipients at the end of each message. Responding with a newline indicates your satisfaction with the current list.
- asksubject** Causes *mail* to prompt you for the subject of each message you send. If you respond with simply a newline, no subject field is sent.
- autombox** Causes all examined messages to be saved in the user mailbox unless deleted or saved.
- autoprint** Causes the **delete** command to behave like **dp** - thus, after deleting a message, the next one will be entered automatically.
- chron** Causes messages to be displayed in chronological order.
- dot** Permits use of dot (.) as the end of file character when composing messages.

execmail	Causes the underbar prompt to return before <i>mail</i> is finished being sent. This frees the user to continue while <i>mail</i> performs mailing functions in background.
ignore	Causes interrupt signals from your terminal to be ignored and echoed as at-signs (@).
mchron	Causes messages to be listed in numerical order (most recently received first), but displayed in chronological order.
metoo	Usually, when a group is expanded that contains the sender, the sender is removed from the expansion. Setting this option causes the sender to be included in the group.
nosave	Prevents aborted messages from being appended to the file <i>dead.letter</i> in your home directory on receipt of two interrupts (or a ~q).
quiet	Suppresses the printing of the version header when first invoked.
verify	Causes each target mail recipient to be verified in the manner described in the <i>whois</i> command. This option permits errors made while composing messages to be corrected or ignored.

The following options have string values:

EDITOR	Pathname of the text editor to use in the <i>edit</i> command and ~e escape. If not defined, then a default editor (<i>/bin/ed</i>) is used.
SHELL	Pathname of the shell to use in the <i>!</i> command and the ~! escape. A default shell (<i>/bin/sh</i>) is used if this option is not defined.
VISUAL	Pathname of the text editor (<i>/bin/vi</i>) to use in the <i>visual</i> command and ~v escape.
escape	If defined, the first character of this option gives the character to use in the place of the tilde (~) to denote escapes.
page=<i>n</i>	Specifies the number of lines (<i>n</i>) to be printed in a "page" of text when displaying messages.
record	If defined, gives the pathname of the file used to record all outgoing mail. If not defined, then outgoing mail is not saved.

toplines If defined, gives the number of lines of a message to be printed out with the **top** command; normally, the first six lines are printed.

Files

/usr/spool/mail/*	System mailboxes
/usr/name/dead.letter	File where undeliverable mail is deposited
/usr/name/mbox	Your old mail
/usr/name/.mailrc	File giving initial mail commands
/usr/lib/mail/aliases	System-wide aliases
/usr/lib/mail/aliases.hash	System-wide alias database
/usr/lib/mail/faliases	Forwarding aliases for the local machine
/usr/lib/mail/maliases	Machine aliases
/usr/lib/mail/mailhelp.cmd	Help file
/usr/lib/mail/mailhelp.esc	Help file
/usr/lib/mail/mailhelp.set	Help file
/usr/lib/mail/mailrc	System initialization file (defaults)
/usr/bin/mail	The mail command

aliases(M), aliashash(M), netutil(C) Chapter 3, "Mail", in the *XENIX User's Guide*.

Credit

This utility was developed at the University of California at Berkeley and is used with permission.

Name

mesg – Permits or denies messages sent to a terminal.

Syntax

mesg [*n*] [*y*]

Description

mesg with argument *n* forbids messages via *write*(C) by revoking nonuser write permission on the user's terminal. *mesg* with argument *y* reinstates permission. All by itself, *mesg* reports the current state without changing it.

Files

/dev/tty*

See Also

write(C)

Diagnostics

Exit status is 0 if messages are receivable, 1 if not, 2 on error.

Name

mkdev - Calls scripts to create devices

Syntax

```
/etc/mkdev lp  
/etc/mkdev hd  
/etc/mkdev serial  
/etc/mkdev fs [ device file ]
```

Description

mkdev calls the scripts to create the requested type of device file(s). *mkdev* calls either *lpinit*(C), *hdinit*, *serinit*, or *fsinit*. If no arguments are listed, *mkdev* prints a usage message.

/etc/mkdev lp creates device files for use with line printers.

/etc/mkdev hd creates device files for use with peripheral hard disks. The device files for an internal hard disk already exist.

/etc/mkdev serial creates device files for use with serial cards. The device files for the first and second ports already exist. Additional device files must be created for the ports added when expansion cards are added to the system.

/etc/mkdev fs performs the system maintenance tasks required to add a new filesystem to the system once the device is created (*mknod*(C)) and the filesystem is made (*mkfs*(C)). It creates the */file* and */file/lost&found* directories, reserves slots in the *lost&found* directory, and modifies */etc/checklist* and */etc/rc* to check (*fsck*(C)) and mount (*mount*(C)) the filesystem as appropriate. It is usually used in conjunction with *mkdev hd* when adding a second hard disk to the system, but can be used on any additional filesystem (for example, on a large internal hard disk or a floppy.)

The various *init* scripts prompt for the information necessary to create the devices.

Files

```
/etc/hdinit  
/etc/lpinit  
/etc/serinit  
/etc/fsinit
```

See Also

lpinit(C), hd(M), lp(M), serial(M), and “Adding a Terminal” in Chapter 7 of the *XENIX Operations Guide*.

Name

mkdir – Makes a directory.

Syntax

mkdir dirname ...

Description

mkdir creates directories. The standard entries “dot” (.), for the directory itself, and “dot dot” (..), for its parent, are made automatically.

mkdir requires write permission in the parent directory. The permissions assigned to the new directory are modified by the current file creation mask set by *umask* (C).

See Also

rmdir(C), *umask*(C)

Diagnostics

mkdir returns exit code 0 if all directories were successfully made; otherwise, it prints a diagnostic and returns nonzero.

Name

mkfs – Constructs a file system.

Syntax

```
/etc/mkfs [ -y ] [ -n ] special blocks[ : inodes] [gap blocks]
/etc/mkfs [ -y ] [ -n ] special proto [gap blocks]
```

Description

mkfs constructs a file system by writing on the special file *special*, according to the directions found in the remainder of the command line.

If it appears that the special file contains a file system, operator confirmation is requested before overwriting the data. The **-y** “yes” option overrides this, and writes over any existing data without question. The **-n** option causes *mkfs* to terminate without question if the target contains an existing file system. The check used is to read block one from the target device (block one is the super-block) and see whether the bytes are the same. If they are not, this is taken to be meaningful data and confirmation is requested.

If the second argument is given as a string of digits, *mkfs* builds a file system with a single empty directory on it. The size of the file system is the value of *blocks* interpreted as a decimal number. The boot program is left uninitialized. If the number of inodes is specified, then this number should be the same as the estimated number of files in the file system. If the optional number of inodes is not given, the number of inodes is calculated as a function of the system file size.

If the second argument is a file name that can be opened, *mkfs* assumes it to be a prototype file *proto*, and takes its directions from that file. The prototype file contains tokens separated by spaces or newlines. The first token is the name of a file to be copied onto block zero as the bootstrap program. The bootstrap program specified should already be stripped of the header (see *strip*(CP)). If the header has not been stripped from the bootstrap program, then *mkfs* issues a warning. The second token is a number specifying the size of the created file system. Typically, it will have been the number of blocks on the device, perhaps diminished by space for swapping. The next token is the i-list size in blocks. The next set of tokens comprise the specification for the root file. File specifications consist of tokens giving the mode, the user ID, the group ID, and the initial contents of the file. The syntax of the contents field depends on the mode.

The mode token for a file is a 6 character string. The first character specifies the type of the file. (The characters **-bcd** specify regular, block special, character special and directory files respectively.) The second character of the type is either **u** or **-** to specify set-user-ID mode or not. The third is **g** or **-** for the set-group-ID mode. The rest of the mode is a three digit octal number giving the owner, group, and other read, write, execute permissions; see *chmod(C)*.

Two decimal number tokens come after the mode; they specify the user and group ID's of the owner of the file.

If the file is a regular file, the next token is a pathname whose contents and size are copied. If the file is a block or character special file, two decimal number tokens follow which give the major and minor device numbers. If the file is a directory, *mkfs* makes the entries **.** and **..** and then reads a list of names and (recursively) file specifications for the entries in the directory. The scan is terminated with the token **\$**.

A sample prototype specification follows:

```
/stand/diskboot
4872 110
d--777 3 1
usr d--777 3 1
  sh ---755 3 1 /bin/sh
  ken d--755 6 1
    $
  b0 b--644 3 1 0 0
  c0 c--644 3 1 0 0
    $
  $
```

In both commands, the disk interleaving factors, *gap* and *blocks*, can be specified. The interleaving factors are a disk hardware function and are described in detail in the *XENIX Operations Guide*.

See Also

chmod(C), *filesystem(F)*, *dir(F)*, *strip(CP)*

Notes

There is no way to specify links when using a prototype file. If the number of inodes is specified on the command line, then the maximum number of inodes in the file system is 65500.

This utility uses BSIZE blocks. Refer to the *machine (HW)* manual page for the size of filesystem blocks.

Name

mknod - Builds special files.

Syntax

/etc/mknod name [**c**] [**b**] major minor

/etc/mknod name **p**

/etc/mknod name **s**

/etc/mknod name **m**

Description

mknod makes a directory entry and corresponding inode for a special file. The first argument is the *name* of the entry. In the first case, the second argument is **b** if the special file is block-type (disks, tape) or **c** if it is character-type (other devices). The last two arguments are numbers specifying the *major* device type and the *minor* device (e.g., unit, drive, or line number), which may be either decimal or octal.

The assignment of major device numbers is specific to each system. Major device numbers can be found in the system source file **c.c**.

mknod can also be used to create named pipes with the **p** option; semaphores with the **s** option; and shared data (memory) with the **m** option.

Only the super-user can use the first form of the syntax.

System Compatibility

The **s** and **m** options can only be used to create XENIX version 3.0 semaphores and shared data, not XENIX System V semaphores and shared data.

See Also

mknod(S)

Name

mkuser – Adds a login ID to the system.

Syntax

/etc/mkuser

Description

mkuser is used to add more user login IDs to the system. It is the preferred method for adding new users to the system, since it handles all directory creation and password file update. To add a new user to the system, *mkuser* requires five pieces of information: the login name, the initial password, the group identification, the user's login shell and an optional comment string for the password file. It also allows the new user to be assigned to a group if required, although in most cases a default group is suitable. The program prompts for these five items and validates the given data. The login name is checked against certain criteria (i.e., it must be at least three characters and begin with a lowercase letter). The password must follow standard XENIX conventions, see *passwd(C)*. The password file comment field can be up to 20 characters of information.

mkuser takes some of its parameters from a default file, */etc/default/mkuser*. Currently, one may set the root path of home directories. An example default file is:

HOME=/usr

This file can be edited (by the super-user) to change this default. There are five other files in the directory */usr/lib* which may also be altered to suit local options. They are *mkuser.help* which is the introductory explanation given by *mkuser* on startup, *mkuser.mail* which is the initial mail message sent to new users, *mkuser.prof*, the standard *.profile* file given to new *sh* and *rsh* shell users, *mkuser.login*, the standard *.login* file given to new *cs*h users, and *mkuser.cshrc*, the standard *.cshrc* file given to new *cs*h users.

mkuser prompts for the shell type to assign to the new user. The shell types available are standard (Bourne) *sh* (option 1), visual shell *vsh* (option 2), c-shell *cs*h (option 3), restricted *rsh* (option 4), and *uucp login* (option 5).

mkuser allocates user IDs starting at 200, or the largest number used in the password file. The default group ID for new users is 50. The minimum group ID allowed for user accounts is 50. The program prompts the operator for an optional group specification. This can either be a numeric group ID, or a group name. If the group exists,

the user is added to it. If it does not exist, a new entry in **/etc/group** is created. A new group cannot have a numeric ID less than 51. If a new group is to be created, and the operator only specifies the group name, a free group ID is assigned. Alternatively, the operator can specify the group ID too.

mkuser can only be executed by the super-user.

The minimum length of a legal password, and the minimum and maximum number of weeks used in password aging are specified in **/etc/default/passwd** by the variables **PASSLENGTH**, **MINWEEKS** and **MAXWEEKS**. For example, these variables might be set as follows:

```
PASSLENGTH=6
MINWEEKS=2
MAXWEEKS=6
```

Files

```
/etc/passwd
/usr/spool/mail/username
/etc/default/mkuser
/etc/default/passwd
/usr/lib/mkuser/mkuser.cshrc
/usr/lib/mkuser/mkuser.help
/usr/lib/mkuser/mkuser.login
/usr/lib/mkuser/mkuser.prof
/usr/lib/mkuser/mkuser.mail
```

chmod(C), group(M), passwd(C), pwadmin(C), rmuser(C)

Name

more - Views a file one screen full at a time.

Syntax

more [*-cdfllrsuw*] [*-n*] [*+linenumber*] [*+ /pattern*] [*name ...*]

Description

This filter allows examination of a continuous text one screen full at a time. It normally pauses after each full screen, displaying:

--More--

at the bottom of the screen. If the user then presses a carriage return, one more line is displayed. If the user presses the SPACE bar, another full screen is displayed. Other possibilities are described below.

The command line options are:

- n* An integer which is the size (in lines) of the window which *more* will use instead of the default.
- c* *more* draws each page by beginning at the top of the screen and erasing each line just before it draws on it. This avoids scrolling the screen, making it easier to read while *more* is writing. This option is ignored if the terminal does not have the ability to clear to the end of a line.
- d* *more* prompts with the message "Hit space to continue, Rubout to abort" at the end of each full screen. This is useful if *more* is being used as a filter in some setting, such as a class, where many users may be inexperienced.
- f* This option causes *more* to count logical, rather than screen lines. That is, long lines are not folded. This option is recommended if *nroff* output is being piped through *ul*, since the latter may generate escape sequences. These escape sequences contain characters that would ordinarily occupy screen positions, but do not print when they are sent to the terminal as part of an escape sequence. Thus *more* may think that lines are longer than they actually are and fold lines erroneously.
- l* Does not treat Ctrl-L (form feed) specially. If this option is not given, *more* pauses after any line that contains a Ctrl-L, as if the end of a full screen has been reached. Also, if a file begins with a form feed, the screen is cleared before the file is printed.

- s Squeezes multiple blank lines from the output, producing only one blank line. Especially helpful when viewing *nroff* output, this option maximizes the useful information present on the screen.
- u Normally, *more* handles underlining, such as that produced by *nroff* in a manner appropriate to the particular terminal: if the terminal can perform underlining or has a stand-out mode, *more* outputs appropriate escape sequences to enable underlining or stand-out mode for underlined information in the source file. The -u option suppresses this processing.
- r Normally, *more* ignores control characters that it does not interpret in some way. The -r option causes these to be displayed as 'C' where "C" stands for any such character.
- w Normally, *more* exits when it comes to the end of its input. With -w however, *more* prompts and waits for any key to be struck before exiting.

+linenumber

Starts up at *linenumber*.

+/pattern

Starts up two lines before the line containing the regular expression *pattern*.

more looks in the file */etc/termcap* to determine terminal characteristics, and to determine the default window size. On a terminal capable of displaying 24 lines, the default window size is 22 lines.

more looks in the environment variable *MORE* to preset any flags desired. For example, if you prefer to view files using the -c mode of operation, the shell command "MORE=-c" in the *.profile* file causes all invocations of *more* to use this mode.

If *more* is reading from a file, rather than a pipe, a percentage is displayed along with the "--More--" prompt. This gives the fraction of the file (in characters, not lines) that has been read so far.

Other sequences which may be entered when *more* pauses, and their effects, are as follows (*i* is an optional integer argument, defaulting to 1):

***i* <space>**

Displays *i* more lines, (or another full screen if no argument is given).

Ctrl-D

Displays 11 more lines (a "scroll"). If *i* is given, then the scroll size is set to *i*.

d Same as Ctrl-D.

iz Same as entering a space except that *i*, if present, becomes the new window size.

is Skips *i* lines and displays a full screen of lines.

if Skips *i* full screens and displays a full screen of lines.

q or Q
Exits from *more*.

= Displays the current line number.

v Starts up the screen editor *vi* at the current line. Note that *vi* may not be available with your system.

h or ?
Help command; Gives a description of all the *more* commands.

i/expr
Searches for the *i*th occurrence of the regular expression *expr*. If there are less than *i* occurrences of *expr*, and the input is a file (rather than a pipe), then the position in the file remains unchanged. Otherwise, a full screen is displayed, starting two lines before the place where the expression was found. The user's erase and kill characters may be used to edit the regular expression. Erasing back past the first column cancels the search command.

in Searches for the *i*th occurrence of the last regular expression entered.

' (Single quotation mark) Goes to the point from which the last search started. If no search has been performed in the current file, this command goes back to the beginning of the file.

!command
Invokes a shell with *command*. The characters % and ! in "command" are replaced with the current filename and the previous shell command respectively. If there is no current filename, % is not expanded. The sequences "\%" and "\!" are replaced by "%" and "!" respectively.

i:n
Skips to the *i*th next file given in the command line (skips to last file if *i* doesn't make sense).

i:p

Skips to the *i* th previous file given in the command line. If this command is given in the middle of printing out a file, *more* goes back to the beginning of the file. If *i* doesn't make sense, *more* skips back to the first file. If *more* is not reading from a file, the bell rings and nothing else happens.

:f Displays the current filename and line number.

:q or :Q

Exits from *more* (same as q or Q).

. Repeats the previous command.

The commands take effect immediately. It is not necessary to enter a carriage return. Up to the time when the command character itself is given, the user may enter the line kill character to cancel the numerical argument being formed. In addition, the user may enter the erase character to redisplay the "--More--(xx%)" message.

The terminal is set to *noecho* mode by this program so that the output can be continuous. What you enter will not show on your terminal, except for the slash (/) and exclamation (!) commands.

If the standard output is not a teletype, *more* acts just like *cat*, except that a header is printed before each file (if there is more than one).

A sample usage of *more* in previewing *nroff* output would be

```
nroff -ms +2 doc.n | more -s
```

Files

/etc/termcap	Terminal data base
/usr/lib/more.help	Help file

See Also

csh(CP), sh(C), environ(M)

Credit

This utility was developed at the University of California at Berkeley and is used with permission.

Notes

The *vi* and *help* options may not be available.

Before displaying a file, *more* attempts to detect whether it is a non-printable binary file such as a directory or executable binary image. If *more* concludes that a file is unprintable, it refuses to print it. However, *more* cannot detect all possible kinds of non-printable files.

Name

mount – Mounts a file structure.

Syntax

/etc/mount [special-device directory [-r]]

/etc/umount special-device

Description

mount announces to the system that a removable file structure is present on *special-device*. The file structure is mounted on *directory*. The *directory* must already exist; it becomes the name of the root of the newly mounted file structure. *directory* should be empty. If *directory* contains files, they will appear to have been removed while the *directory* is mounted and reappear when the *directory* is unmounted.

The *mount* and *umount* commands maintain a table of mounted devices. If each special device is invoked without any arguments, *mount* displays the name of the device, and the directory name of the mounted file structure, whether the file structure is read-only, and the date it was mounted.

The optional last argument indicates that the file is to be mounted read-only. Physically write-protected file structures must be mounted in this way or errors occur when access times are updated, whether or not any explicit write is attempted.

umount removes the removable file structure previously mounted on device *special-device*.

Files

/etc/mnttab Mount table

See Also

umount(C), mount(S), mnttab(F)

Diagnostics

mount issues a warning if the file structure to be mounted is currently mounted under another name.

Busy file structures cannot be dismounted with *umount*. A file structure is busy if it contains an open file or some user's working directory.

Notes

Some degree of validation is done on the file structure, however it is generally unwise to mount corrupt file structures.

Be warned that when in single-user mode, the commands that look in */etc/mnttab* for default arguments (for example *df*, *ncheck*, *quot*, *mount*, and *umount*) give either incorrect results (due to a corrupt */etc/mnttab* from a non-shutdown stoppage) or no results (due to an empty *mnttab* from a *shutdown* stoppage).

When multi-user, this is not a problem; */etc/rc* initializes */etc/mnttab* to contain only */dev/root* and subsequent mounts update it appropriately.

The *mount(C)* and *umount(C)* commands use a lock file to guarantee exclusive access to */etc/mnttab*. The commands which just read it (those mentioned above) do not, so it is possible that they may hit a window, which is corrupt. This is not a problem in practice since *mount* and *umount* are not frequent operations.

When mounting a file system on a floppy disk you need not use the same *directory* each time. However, if you do, the full pathnames for the files are consistent with each use.

Floppy disks must be unprotected (no write-protect tab) to be mounted as a filesystem. Always **unmount** filesystems on floppy disks before removing them from the floppy drive. Failure to do so requires running **fsck** the next time the disk is **mounted** .

Name

mv - Moves or renames files and directories.

Syntax

mv [-f] file1 file2

mv [-f] file ... directory

Description

mv moves (changes the name of) *file1* to *file2*.

If *file2* already exists, it is removed before *file1* is moved. If *file2* has a mode which forbids writing, *mv* prints the mode (see *chmod*(S)) and reads the standard input to obtain a line. If the line begins with *y*, the move takes place; if not, *mv* exits.

In the second form, one or more *files* are moved to the *directory* with their original filenames.

No questions are asked when the -f option is given.

mv refuses to move a file onto itself.

See Also

cp(C), *chmod*(S), *copy*(C)

Notes

If *file1* and *file2* lie on different file systems, *mv* must copy the file and delete the original. In this case the owner name becomes that of the copying process and any linking relationship with other files is lost.

Name

ncheck - Generates names from inode numbers.

Syntax

ncheck [-i numbers] [-a] [-s] [file-system]

Description

ncheck with no argument generates a pathname and inode number list of all files on the set of file systems specified in */etc/mnttab*. The two characters “/.” are appended to the names of directory files. The *-i* option reduces the report to only those files whose inode numbers follow. The *-a* option allows printing of the names . and .., which are ordinarily suppressed. The *-s* option reduces the report to special files and files with set-user-ID mode; it is intended to discover concealed violations of security policy. A single *filesystem* may be specified rather than the default list of mounted file systems.

Files

/etc/mnttab

See Also

fsck(C), sort(C)

Diagnostics

When the file system structure is improper, ?? denotes the “parent” of a parentless file and a pathname beginning with ... denotes a loop.

Notes

See *Notes* under *mount*(C).

Name

netutil – Administers the XENIX network.

Syntax

netutil [-x] [-e] [-option]

Description

The *netutil* command allows the user to create and maintain a network of XENIX machines. A Micnet network is a link through serial lines of two or more XENIX systems. It is used to send mail between systems with the *mail*(C) command, transfer files between systems with the *rcp*(C) command, and execute commands from a remote system with the *remote*(C) command.

The *netutil* command is used to create and distribute the data files needed to implement the network. It is also used to start and stop the network. The *option* argument may be any one of **install**, **save**, **restore**, **start**, **stop**, or the numbers 1 through 5 respectively. The **-x** option logs transmissions and the **-e** options logs errors.

The **install** option interactively creates the data files needed to run the network. The **save** option saves these files on floppy or hard disks, allowing them to be distributed to the other systems in the network. If you save the micnet files to the hard disk, you can then use *uucp*(C) to transfer the files to the other machines. This option specifies the name of the backup device and prompts for whether this is the desired device to use. The user can specify an alternate device, including a file on the hard disk. The name of the default backup device is located in the file */etc/default/micnet*. This can be changed depending on system configuration. The **restore** option copies the data files from floppy disk back to a system. The **start** option starts the network. The **stop** option stops the network. An *option* may also be any decimal digit in the range 1 to 5. If invoked without an *option*, the command displays a menu from which to choose one. Once an option is selected, it prompts for additional information if needed.

A network must be installed before it can be started. Installation consists of creating appropriate configuration files with the **install** option. This option requires the name of each machine in the network, the serial lines to be used to connect the machines, the speed of transmission for each line, and the names of the users on each machine. Once created, the files must be distributed to each computer in the network with the **save** and **restore** options. The network is started by using the **start** option on each machine in the network. Once started, mail and remote commands can be passed along the network. A record of the transmissions between computers in a network can be kept in the network log files. Installation of the network is described in the *XENIX Operations Guide*.

XENIX Operations Guide

Name

newform – Changes the format of a text file.

Syntax

```
newform [-s] [-itabspec] [-otabspec] [-bn] [-en] [-pn] [-an] [-f]
[-cchar] [-ln] [file ... ]
```

Description

newform reads lines from the named *files*, or the standard input if no input file is named, and reproduces the lines on the standard output. Lines are reformatted in accordance with command line options in effect.

Except for *-s*, command line options may appear in any order, may be repeated, and may be intermingled with *files*. Command line options are processed in the order typed. This means that option sequences like “*-e15 -l60*” will yield results different from “*-l60 -e15*”. Options are applied to all *files* on the command line.

- itabspec* Input tab specification: expands tabs to spaces, according to the tab specifications given. *Tabspec* recognizes all tab specification forms described below. In addition, *tabspec* may be *--*, in which *newform* assumes that the tab specification is to be found in the first line read from the standard input. If no *tabspec* is given, *tabspec* defaults to *-8*. A *tabspec* of *-0* expects no tabs; if any are found, they are treated as *-1*.
- otabspec* Output tab specification: replaces spaces by tabs, according to the tab specifications given. The tab specifications are the same as for *-itabspec*. If no *tabspec* is given, *tabspec* defaults to *-8*. A *tabspec* of *-0* means that no spaces will be converted to tabs on output.
- ln* Sets the effective line length to *n* characters. If *n* is not typed, *-l* defaults to 72. The default line length without the *-l* option is 80 characters. Note that tabs and backspaces are considered to be one character (use *-i* to expand tabs to spaces).
- bn* Truncates *n* characters from the beginning of the line when the line length is greater than the effective line length (see *-ln*). The default is to truncate the number of characters necessary to obtain the effective line length. The default value is used when *-b* with no *n* is used. This option can be used to delete the sequence

numbers from a COBOL program as follows:
 newform -l1 -b7 file-name

The option **-l1** must be used to set the effective line length shorter than any existing line in the file so that the **-b** option is activated.

- en** Truncates *n* characters from the end of the line.
- ck** Changes the prefix/append character to *k*. Default character for *k* is a space (see options **-p** and **-c**).
- pn** Prefixes *n* characters (see **-ck**) to the beginning of a line when the line length is less than the effective line length. The default is to prefix the number of characters necessary to obtain the effective line length.
- an** Appends *n* characters to the end of a line. The default is to append the number of characters necessary to get the effective line length.
- f** Writes the tab specification format line on the standard output before any other lines are output. The tab specification format line which is printed will correspond to the format specified in the *last -o* option. If no **-o** option is specified, the line which is printed will contain the default specification of **-8**.
- s** Shears off leading characters on each line up to the first tab and places up to 8 of the sheared characters at the end of the line. If more than 8 characters (not counting the first tab) are sheared, the eighth character is replaced by a * and any characters to the right of it are discarded. The first tab is always discarded.

An error message and program exit will occur if this option is used on a file without a tab on each line. The characters sheared off are saved internally until all other options specified are applied to that line. The characters are then added at the end of the processed line.

Tabs

Four types of tab specification are accepted for *tabspec*: "canned," repetitive, arbitrary, and file. The lowest column number is 1. For *tabs*, column 1 always refers to the leftmost column on a terminal, even one whose column markers begin at 0, e.g. the DASI 300, DASI 300S, and DASI 450.

The "canned" tabs are given as *-code* where *code* (and its meaning) is from the following list:

- a 1,10,16,36,72
 Assembler, IBM S/370, first format
- a2 1,10,16,40,72
 Assembler, IBM S/370, second format
- c 1,8,12,16,20,55
 COBOL, normal format
- c2 1,6,10,14,49
 COBOL compact format (columns 1-6 omitted). Using this code, the first typed character corresponds to card column 7, one space gets you to column 8, and a tab reaches column 12. Files using this tab setup should include a format specification as follows:
 <:t-c2 m6 s66 d:>
- c3 1,6,10,14,18,22,26,30,34,38,42,46,50,54,58,62,67
 COBOL compact format (columns 1-6 omitted), with more tabs than COBOL -c2. This is the recommended format for COBOL. The appropriate format specification is:
 <:t-c3 m6 s66 d:>
- f 1,7,11,15,19,23
 FORTRAN
- p 1,5,9,13,17,21,25,29,33,37,41,45,53,57,61
 PL/I
- s 1,10,55
 SNOBOL
- u 1,12,20,44
 UNIVAC 1100 Assembler

In addition to these "canned" formats, three other types exist:

- n A repetitive specification requests tabs at columns 1+n, 1+2*n, etc. Note that such a setting leaves a left margin of *n* columns on TermiNet terminals *only*. Of particular importance is the value -8: this represents the XENIX system "standard" tab setting, and is the most likely tab setting to found at a terminal. It is required for use with *nroff*(CT) -h option for high-speed output. Another special case is the value -0, implying no tabs at all.

n1,n2,... The arbitrary format permits the user to type any chosen set of number, separated by commas, in ascending order. Up to 40 numbers are allowed. If any number (except the first one) is preceded by a plus sign, it is taken as an increment to be added to the previous value. Thus, the tab lists 1,10,20,30 and 1,10,+10,+10 are considered identical.

- *-file*

If the name of a file is given, *newform* reads the first line of the file, searching for a format specification. If it finds one there, it sets the tab stops according to it, otherwise it sets them as -8. This type of specification may be used to make sure that a tabbed file is printed with correct tab settings.

Any of the following may be used also; if a given flag occurs more than once, the last value given takes effect:

- *Type*

newform usually needs to know the type of terminal in order to set tabs and always needs to know the type to set margins. *type* is a name listed in *term*(CT). If no -T flag is supplied, *newform* searches for the \$TERM value in the *environment* (see *environ*(M)). If no *type* can be found, *newform* tries a sequence that will work for many terminals.

+ *mn*

The margin argument may be used for some terminals. It causes all tabs to be moved over *n* columns by making column *n*+1 the left margin. If +*m* is given without a value of *n*, the value assumed is 10. For a TerminiNet, the first value in the tab list should be 1, or the margin will move even further to the right. The normal (leftmost) margin on most terminals is obtained by +*m*0. The margin for most terminals is reset only when the +*m* flag is given explicitly.

Example

In the following example, *newform* converts a file named *text* with leading digits, one or more tabs, and text on each line to a file beginning with the text and the leading digits placed at the end of each line in column 73 (-s option). All tabs after the first one are expanded to spaces (-i option). To reach the line length of 72 characters (-l option), spaces are appended to each line up to column 72 (-a option) or lines are truncated at column 72 (-e option). To reformat the sample file *text* in this manner, enter:

```
newform -s -i -l -a -e text
```

Exit Codes

0 - normal execution
1 - for any error

See Also

csplit(C)

Diagnostics

All diagnostics are fatal.

usage: . . .

not -s format

can't open file

internal line too long

tabspec in error

tabspec indirection illegal

newform was called with a bad option.

There was no tab on one line.

Self-explanatory.

A line exceeds 512 characters after being expanded in the internal work buffer.

A tab specification is incorrectly formatted, or specified tab stops are not ascending.

A *tabspec* read from a file (or standard input) may not contain a *tabspec* referencing another file (or standard input).

Notes

newform normally only keeps track of physical characters; however, for the **-i** and **-o** options, *newform* will keep track of backspaces in order to line up tabs in the appropriate logical columns.

newform will not prompt the user if a *tabspec* is to be read from the standard input (by use of **-i,-** or **-o,-**).

If the **-f** option is used, and the last **-o** option specified was **"-o--"**, and was preceded by either **"-o--"** or a **"-i--"**, the tab specification format line will be incorrect.

Name

newgrp – Logs user in to a new group.

Syntax

newgrp [group]

Description

newgrp changes the group identification of its caller. The same person remains logged in, and the current directory is unchanged, but calculations of access permissions to files are performed with respect to the new group ID.

newgrp without an argument changes the group identification to the group in the password file; in effect it changes the group identification back to the caller's original group.

A password is demanded if the group has a password and the user himself does not, or if the group has a password and the user is not listed in */etc/group* as being a member of that group.

When most users log in, they are members of the group named **group**.

Files

/etc/group

/etc/passwd

See Also

login(M), group(M)

Notes

There is no convenient way to enter a password into */etc/group*.

Use of group passwords is not encouraged, because, by their very nature, they encourage poor security practices. Shell variables are not preserved when invoking this command unless they are explicitly exported.

Name

news - Print news items.

Syntax

news [*-a*] [*-n*] [*-s*] [*items*]

Description

news is used to keep the user informed of current events. By convention, these events are described by files in the directory */usr/news*.

When invoked without arguments, *news* prints the contents of all current files in */usr/news*, most recent first, with each preceded by an appropriate header. *news* stores the "currency" time as the modification date of a file named *.news_time* in the user's home directory (the identity of this directory is determined by the environment variable *\$HOME*); only files more recent than this currency time are considered "current."

The *-a* option causes *news* to print all items, regardless of currency. In this case, the stored time is not changed.

The *-n* option causes *news* to report the names of the current items without printing their contents, and without changing the stored time.

The *-s* option causes *news* to report how many current items exist, without printing their names or contents, and without changing the stored time.

All other arguments are assumed to be specific news items that are to be printed.

If the INTERRUPT key is struck during the printing of a news item, printing stops and the next item is started. Another INTERRUPT within one second of the first causes the program to terminate.

Files

/usr/news/*
\$HOME/.news_time

See Also

profile(M), environ(M).

Name

`nice` – Runs a command at a different priority.

Syntax

`nice [-increment] command [arguments]`

Description

nice executes *command* with a lower CPU scheduling priority. Priorities range from 0 to 39, where 0 is the highest priority and 39 is the lowest. By default, commands have a "nice value" of 20. If an **-increment** argument is given where *increment* is in the range 1-19, *increment* is added to the default priority of 20 to produce a numerically higher priority, meaning a *lower* scheduling priority. If no *increment* is given, an increment of 10 to produce a priority of 30 is assumed.

The super-user may run commands with priority *higher* than normal by using a double negative increment. For example, an argument of **- -10** would decrement the default to produce a nice value of 10, which is a higher scheduling priority than the default of 20.

See Also

`nohup(C)`, `nice(S)`

Diagnostics

nice returns the exit status of the subject command.

Notes

An *increment* larger than 19 is equivalent to 19.

Name

`nl` – Adds line numbers to a file.

Syntax

`nl [-htype] [-btype] [-ftype] [-vstart#] [-iincr] [-p] [-lnum]
[-ssep] [-wwidth] [-nformat] file`

Description

nl reads lines from the named *file*, or the standard input if no *file* is named, and reproduces the lines on the standard output. Lines are numbered on the left in accordance with the command options in effect.

nl views the text it reads in terms of logical pages. Line numbering is reset at the start of each logical page. A logical page consists of a header, a body, and a footer section. Empty sections are valid. Different line numbering options are independently available for header, body, and footer (e.g. no numbering of header and footer lines while numbering blank lines only in the body).

The start of logical page sections is signaled by input lines containing nothing but the following character(s):

<i>Page Section</i>	<i>Line Contents</i>
Header	\\:\:
Body	\\:\:
Footer	\\:

Unless signaled otherwise, *nl* assumes the text being read is in a single logical page body.

Command options may appear in any order and may be intermingled with an optional filename. Only one file may be named. The options are:

-b_{type} Specifies which logical page body lines are to be numbered. Recognized *types* and their meaning are: **a**, number all lines; **t**, number lines with printable text only; **n**, no line numbering; **pstring**, number only lines that contain the regular expression specified in *string*. Default *type* for logical page body is **t** (text lines numbered).

- h \textit{type}** Same as **-b \textit{type}** except for header. Default \textit{type} for logical page header is **n** (no lines numbered).
- f \textit{type}** Same as **-b \textit{type}** except for footer. Default for logical page footer is **n** (no lines numbered).
- p** Does not restart numbering at logical page delimiters.
- vstart#** *Start#* is the initial value used to number logical page lines. Default is **1**.
- incr** *Incr* is the increment value used to number logical page lines. Default is **1**.
- ss \textit{sep}** *Sep* is the character(s) used in separating the line number and the corresponding text line. Default *sep* is a tab.
- ww \textit{width}** *Width* is the number of characters to be used for the line number. Default *width* is **6**.
- nformat** *Format* is the line numbering format. Recognized values are: **ln**, left justified, leading zeroes suppressed; **rn**, right justified, leading zeroes suppressed; **rz**, right justified, leading zeroes kept. Default *format* is **rn** (right justified).
- l \textit{num}** *Num* is the number of blank lines to be considered as one. For example, **-12** results in only the second adjacent blank being numbered (if the appropriate **-ha**, **-ba**, and/or **-fa** option is set). Default is **1**.

pr(C)

Name

nohup – Runs a command immune to hangups and quits.

Syntax

nohup command [arguments]

Description

nohup executes *command* with hangups and quits ignored. If output is not redirected by the user, it will be sent to **nohup.out**. If **nohup.out** does not have write permission in the current directory, output is redirected to **\$HOME/nohup.out**.

See Also

nice(C), **signal**(S)

Name

od - Displays files in octal format.

Syntax

od [**-bcdox**] [*file*] [[**+**]offset[.][**b**]]

Description

od displays *file* in one or more formats as selected by the first argument. If the first argument is missing, **-o** is default. The meanings of the format options are:

- b** Interprets bytes in octal.
- c** Interprets bytes in ASCII. Certain nongraphic characters appear as C escapes: null=**\0**, backspace=**\b**, form feed=**\f**, newline=**\n**, return=**\r**, tab=**\t**; others appear as 3-digit octal numbers.
- d** Interprets words in decimal.
- o** Interprets words in octal.
- x** Interprets words in hex.

The *file* argument specifies which file is to be displayed. If no file argument is specified, the standard input is used.

The offset argument specifies the offset in the file where displaying is to start. This argument is normally interpreted as octal bytes. If **.** is appended, the offset is interpreted in decimal. If **b** is appended, the offset is interpreted in blocks. If the file argument is omitted, the offset argument must be preceded by **+**.

The display continues until end-of-file.

See Also

hd(C), adb(CP)

Name

pack, **pcat**, **unpack** – Compresses and expands files.

Syntax

pack [-] *name* ...

pcat *name* ...

unpack *name* ...

Description

pack attempts to store the specified files in a compressed form. Wherever possible, each input file *name* is replaced by a packed file *name.z* with the same access modes, access and modified dates, and the owner of *name*. If *pack* is successful, *name* will be removed. Packed files can be restored to their original form using *unpack* or *pcat*.

pack uses Huffman (minimum redundancy) codes on a byte-by-byte basis. If the - argument is used, an internal flag is set that causes the number of times each byte is used, its relative frequency, and the code for the byte to be printed on the standard output. Additional occurrences of - in place of *name* will cause the internal flag to be set and reset.

The amount of compression obtained depends on the size of the input file and the character frequency distribution. Because a decoding tree forms the first part of each .z file, it is usually not worthwhile to pack files smaller than three blocks, unless the character frequency distribution is very scattered, which may occur with printer plots or pictures.

Typically, text files are reduced to 60-75% of their original size. Load modules, which use a larger character set and have a more uniform distribution of characters, show little compression, the packed versions being about 90% of the original size.

pack returns a value that is the number of files that it failed to compress.

No packing will occur if:

- The file appears to be already packed
- The filename has more than 12 characters

- The file has links
- The file is a directory
- The file cannot be opened
- No disk storage blocks will be saved by packing
- A file called *name.z* already exists
- The *.z* file cannot be created
- An I/O error occurred during processing

The last segment of the filename must contain no more than 12 characters to allow space for the appended *.z* extension. Directories cannot be compressed.

Pcat does for packed files what *cat*(C) does for ordinary files. The specified files are unpacked and written to the standard output. Thus to view a packed file named *name.z* use:

```
pcat name.z
```

or just:

```
pcat name
```

To make an unpacked copy, say *nnn*, of a packed file named *name.z* without destroying *name.z*, enter the command:

```
pcat name >nnn
```

Pcat returns the number of files it was unable to unpack. Failure may occur if:

- The filename (exclusive of the *.z*) has more than 12 characters
- The file cannot be opened
- The file does not appear to be the output of *pack*

Unpack expands files created by *pack*. For each file *name* specified in the command, a search is made for a file called *name.z* (or just *name*, if *name* ends in *.z*). If this file appears to be a packed file, it is replaced by its expanded version. The new file has the *.z* suffix stripped from its name, and has the same access modes, access and modification dates, and owner as those of the packed file.

Unpack returns a value that is the number of files it was unable to unpack. Failure may occur for the same reasons that it may in *pcat*, as well as in a file where the “unpacked” name already exists, or if the unpacked file cannot be created.

Name

passwd – Changes login password.

Syntax

passwd name

Description

This command changes (or installs) a password associated with the login *name*.

The program prompts for the old password (if any) and then for the new one (twice). The user must supply these. Passwords can be of any reasonable length, but only the first eight characters of the password are significant. The minimum number of characters allowed in a new password is determined by the PASSLENGTH variable. Although the minimum can be 3, a minimum of 5 characters is strongly recommended since passwords shorter than this are much easier to guess or discover by trial and error.

Only the owner of the name or the super-user may change a password; the owner must prove he knows the old password. Only the super-user can create a null password.

The password file is not changed if the new password is the same as the old password, or if the password has not “aged” sufficiently; see *passwd(M)*.

The minimum length of a legal password, and the minimum and maximum number of weeks used in password aging are specified in */etc/default/passwd* by the variables PASSLENGTH, MINWEEKS and MAXWEEKS. If not explicitly set, the default values for these variables are:

```
PASSLENGTH=5
MINWEEKS=2
MAXWEEKS=4
```

MINWEEKS and MAXWEEKS values must be in the range 0 to 63. If PASSLENGTH is not in the range 3 to 8, it is set to 5.

Files

```
/etc/default/passwd
/etc/passwd
```

default(M), login(M), passwd(M), pwadmin(C)

Name

pg - File perusal filter for soft-copy terminals.

Syntax

```
pg [- number ] [- p string ] [- cefns] [+ linenumber ] [+ / pattern /]  
[ files ...]
```

Description

The **pg** command is a filter which allows the examination of *files* one screenful at a time on a soft-copy terminal. (The dash (-) command line option and/or NULL arguments indicate that **pg** should read from the standard input.) Each screenful is followed by a prompt. If you press the RETURN key, another page is displayed; other possibilities are listed below. This command is different from previous paginators because it allows you to back up and review something that has already passed.

To determine terminal attributes, **pg** scans the *termcap*(M) data base for the terminal type specified by the environment variable **TERM**. If **TERM** is not defined, the terminal type **dumb** is assumed.

The command line options are:

- *number* Specifies the size (in lines) of the window that **pg** is to use instead of the default. (On a terminal containing 24 lines, the default window size is 23.)
- **p** *string* Causes **pg** to use *string* as the prompt. If the prompt string contains a "%d", the first occurrence of "%d" in the prompt will be replaced by the current page number when the prompt is issued. The default prompt string is a colon (:).
- **c** Homes the cursor and clears the screen before displaying each page. This option is ignored if **clear_screen** is not defined for this terminal type in the *termcap*(M) data base.
- **e** Causes **pg** *not* to pause at the end of each file.
- **f** Inhibits **pg** from splitting lines. In the absence of the -**f** option, **pg** splits lines longer than the screen width, but some sequences of characters in the displayed text (for example, escape sequences for underlining) give undesirable results.

- n Normally, commands must be terminated by pressing the RETURN key (ASCII newline character). This option causes an automatic end of command as soon as a command letter is entered.
- s Causes *pg* to display all messages and prompts in stand-out mode (usually inverse video).
- +*linenumber* Starts up at *linenumber*.
- +*/pattern/* Starts up at the first line containing the regular expression pattern.

The responses that may be entered when *pg* pauses can be divided into three categories: those that cause further perusal, those that search, and those that modify the perusal environment.

Commands which cause further perusal normally take a preceding *address* (an optionally signed number indicating the point from which further text should be displayed). *pg* interprets this *address* in either pages or lines depending on the command. A signed *address* specifies a point relative to the current page or line, and an unsigned *address* specifies an address relative to the beginning of the file. Each command has a default address if no address is provided.

The perusal commands and their defaults are as follows:

- (+1) RETURN key or <*blank*>
Causes one page to be displayed. The *address* is specified in pages.
- (+1) l
With a signed *address*, causes *pg* to simulate scrolling the screen, forward or backward, the number of lines specified. With an unsigned *address* this command displays a full screen of text beginning at the specified line.
- (+1) d or Ctrl-D
Simulates scrolling half a screen forward or backward.

The following perusal commands take no *address*:

- . or Ctrl-L
Causes the current page of text to be redisplayed.
- \$ Displays the last window full in the file. Use with caution when the input is a pipe.

The following commands are available for searching for text patterns in the text. The regular expressions described in *ed(C)* are available. They must always be terminated by a newline character, even if the *-n* option is specified.

i/pattern/

Search forward for the *i*th (default *i*=1) occurrence of *pattern*. Searching begins immediately after the current page and continues to the end of the current file, without wrap-around.

***i^pattern^*
*i?pattern?***

Search backwards for the *i*th (default *i*=1) occurrence of *pattern*. Searching begins immediately before the current page and continues to the beginning of the current file, without wrap-around. The caret (^) notation is useful for terminals which will not properly handle the question mark (?).

After searching, *pg* displays the line found at the top of the screen. You can modify this by appending *m* or *b* to the search command to leave the line found in the middle or at the bottom of the window from now on. Use the suffix *t* to restore the original situation.

The following commands modify the environment of perusal:

in Begins perusing the *i*th next file in the command line. The *i* is an unsigned number, default value is 1.

ip Begins perusing the *i*th previous file in the command line. The *i* is an unsigned number, default is 1.

iw Displays another window of text. If *i* is present, set the window size to *i*.

s filename

Saves the input in the named file. Only the current file being perused is saved. The white space between the *s* and *filename* is optional. This command must always be terminated by a newline character, even if the *-n* option is specified.

h Help displays abbreviated summary of available commands.

q* or *Q Quit *pg*.

!command

command is passed to the shell, whose name is taken from the *SHELL* environment variable. If this is not available, the default shell is used. This command must always be terminated by a newline character, even if the *-n* option is specified.

At any time when output is being sent to the terminal, the user can press the quit key (normally Ctrl-\) or the INTERRUPT (BREAK) key. This causes *pg* to stop sending output, and display the prompt. The user may then enter one of the above commands in the normal manner. Unfortunately, some output is lost when this is done, because any characters waiting in the terminal's output queue are flushed when the quit signal occurs.

If the standard output is not a terminal, then *pg* acts just like *cat*(C), except that a header is printed before each file (if there is more than one).

Example

To use *pg* to read system news, enter:

```
news | pg -p "(Page %d):"
```

Files

/etc/termcap	Terminal information data base
/tmp/pg*	Temporary file when input is from a pipe

See Also

ed(C), *grep*(C), *termcap*(M)

Notes

If terminal tabs are not set every eight positions, undesirable results may occur.

When using *pg* as a filter with another command that changes the terminal I/O options terminal settings may not be restored correctly.

While waiting for terminal input, *pg* responds to "BREAK, DEL," and the caret (^) by terminating execution. Between prompts, however, these signals interrupt *pg*'s current task and place you in prompt mode. Use these signals with caution when input is being read from a pipe, since an interrupt is likely to terminate the other commands in the pipeline.

The *z* and *f* commands used with *more* are available, and the terminal slash (/), caret (^), or question mark (?) may be omitted from the searching commands.

The *z* and *f* commands used with *more* are available, and the terminal slash (/), caret (^), or question mark (?) may be omitted from the searching commands.

Name

`pr` – Prints files on the standard output.

Syntax

`pr [options] [files]`

Description

`pr` prints the named files on the standard output. If *file* is `-`, or if no files are specified, the standard input is assumed. By default, the listing is separated into pages, each headed by the page number, date and time, and the name of the file.

By default, columns are of equal width, separated by at least one space; lines which do not fit are truncated. If the `-s` option is used, lines are not truncated and columns are separated by the separation character.

If the standard output is associated with a terminal, error messages are withheld until `pr` has completed printing.

Options may appear singly or combined in any order. Their meanings are:

- `+k` Begins printing with page *k* (default is 1).
- `-k` Produces *k*-column output (default is 1). The options `-e` and `-i` are assumed for multicolumn output.
- `-a` Prints multicolumn output across the page.
- `-m` Merges and prints all files simultaneously, one per column (overrides the `-k`, and `-a` options).
- `-d` Double-spaces the output.
- `-eck` Expands *input* tabs to character positions *k*+1, 2**k*+1, 3**k*+1, etc. If *k* is 0 or is omitted, default tab settings at every 8th position are assumed. Tab characters in the input are expanded into the appropriate number of spaces. If *c* (any nondigit character) is given, it is treated as the input tab character (default for *c* is the tab character).
- `-ick` In *output*, replaces whitespace wherever possible by inserting tabs to character positions *k*+1, 2**k*+1, 3**k*+1, etc. If *k* is 0 or is omitted, default tab settings at every 8th position are assumed. If *c* (any nondigit character) is given, it is

treated as the output tab character (default for *c* is the tab character).

- nck** Provides *k*-digit line numbering (default for *k* is 5). The number occupies the first *k*+1 character positions of each column of normal output or each line of **-m** output. If *c* (any nondigit character) is given, it is appended to the line number to separate it from whatever follows (default for *c* is a tab).
- wk** Sets the width of a line to *k* character positions (default is 72 for equal-width multicolumn output, no limit otherwise).
- ok** Offsets each line by *k* character positions (default is 0). The number of character positions per line is the sum of the width and offset.
- lk** Sets the length of a page to *k* lines (default is 66).
- h** Uses the next argument as the header to be printed instead of the filename.
- p** Pauses before beginning each page if the output is directed to a terminal (*pr* will ring the bell at the terminal and wait for a carriage return).
- f** Uses form feed character for new pages (default is to use a sequence of linefeeds). Pauses before beginning the first page if the standard output is associated with a terminal.
- r** Prints no diagnostic reports on failure to open files.
- t** Prints neither the 5-line identifying header nor the 5-line trailer normally supplied for each page. Quits printing after the last line of each file without spacing to the end of the page.
- sc** Separates columns by the single character *c* instead of by the appropriate number of spaces (default for *c* is a tab).

Examples

The following prints *file1* and *file2* as a double-spaced, three-column listing headed by "file list":

```
pr -3dh "file list" file1 file2
```

PR (C)

PR (C)

The following writes **file1** on **file2**, expanding tabs to columns 10, 19, 28, 37, . . . :

```
pr -e9 -t <file1 >file2
```

See Also

cat(C)

Name

ps - Reports process status.

Syntax

ps [options]

Description

ps prints certain information about active processes. Without *options*, information is printed about processes associated with the current terminal. Otherwise, the information that is displayed is controlled by the following *options*:

- e Prints information about all processes.
- d Prints information about all processes, except process group leaders.
- a Prints information about all processes, except process group leaders and processes not associated with a terminal.
- f Generates a *full* listing. (Normally, a short listing containing only process ID, terminal ("tty") identifier, cumulative execution time, and the command name is printed.) See below for meaning of columns in a full listing.
- l Generates a *long* listing. See below.
- c *corefile* Uses the file *corefile* in place of */dev/mem*.
- s *swapdev* Uses the file *swapdev* in place of */dev/swap*. This is useful when examining a *corefile*.
- n *namelist* The argument is taken as the name of an alternate *namelist* (*/xenix* is the default).
- t *tlist* Restricts listing to data about the processes associated with the terminals given in *tlist*, where *tlist* can be in one of two forms: a list of terminal identifiers separated from one another by a comma, or a list of terminal identifiers enclosed in double quotes and separated from one another by a comma and/or one or more spaces.

- p *plist*** Restricts listing to data about processes whose process ID numbers are given in *plist*, where *plist* is in the same format as *tlist*.
- u *ulist*** Restricts listing to data about processes whose user ID numbers or login names are given in *ulist*, where *ulist* is in the same format as *tlist*. In the listing, the numerical user ID is printed unless the **-f** option is used, in which case the login name is printed.
- g *glist*** Restricts listing to data about processes whose process groups are given in *glist*, where *glist* is a list of process group leaders and is in the same format as *tlist*.

The column headings and the meaning of the columns in a *ps* listing are given below; the letters **f** and **l** indicate the option (*full* or *long*) that causes the corresponding heading to appear; **all** means that the heading always appears. Note that these two options only determine what information is provided for a process; they do *not* determine which processes will be listed.

F	(l)	A status word consisting of flags associated with the process. Each flag is associated with a bit in the status word. These flags are added to form a single octal number. Process flag bits and their meanings are: <ul style="list-style-type: none"> 01 in core; 02 system process; 04 locked in core (e.g., for physical I/O); 10 being swapped; 20 being traced by another process.
S	(l)	The state of the process: <ul style="list-style-type: none"> 0 non-existent; S sleeping; W waiting; R running; I intermediate; Z terminated; T stopped.
UID	(f,l)	The user ID number of the process owner; the login name is printed under the -f option.
PID	(all)	The process ID of the process; it is possible to kill a process if you know this datum.
PPID	(f,l)	The process ID of the parent process.
C	(f,l)	Processor utilization for scheduling.
STIME	(f)	Starting time of the process.
PRI	(l)	The priority of the process; higher numbers mean lower priority.
NI	(l)	Nice value; used in priority computation.
ADDR	(l)	The memory address of the process, if resident; otherwise, the disk address.

SZ	(l)	The size in blocks of the core image of the process, but not including the size of text shared with other processes. Since this size includes the current size of the stack, it will vary as the stack size varies.
WCHAN	(l)	The event for which the process is waiting or sleeping; if blank, the process is running.
TTY	(all)	The controlling terminal for the process.
TIME	(all)	The cumulative execution time for the process.
CMD	(all)	The command name; the full command name and its arguments are printed under the -f option.

A process that has exited and has a parent, but has not yet been waited for by the parent, is marked **<defunct>**.

Under the **-f** option, *ps* tries to determine the command name and arguments given when the process was created by examining memory or the swap area. Failing this, the command name, as it would appear without the **-f** option, is printed in square brackets.

Files

/xenix system namelist

/dev/mem memory

/dev searched to find swap device and terminal ("tty") names.

See Also

kill(C), nice(C)

Notes

Things can change while *ps* is running; the picture it gives is only a close approximation to reality.

Some data printed for defunct processes are irrelevant.

Name

pstat - Reports system information.

Syntax

```
pstat [ -aixptf ] [ -u ubase ] [ -c corefile ]
[ -n namelist ] [ file ]
```

Description

pstat interprets the contents of certain system tables. *pstat* searches for these tables in */dev/mem* and */dev/kmem*. With the *file* given, the tables are sought in the specified *file* rather than */dev/mem*. Similarly, the *-c* option allows one to specify a *corefile* rather than */dev/kmem* for the search. The required namelist is taken from */xenix*. Options are:

- a** Under **-p**, describe all process slots rather than just active ones.
- i** Print the inode table with these headings:
 - LOC The core location of this table entry.
 - FLAGS Miscellaneous state variables encoded thus:
 - L Locked
 - U Update time *filesystem*(F) must be corrected
 - A Access time must be corrected
 - M File system is mounted here
 - W Wanted by another process (L flag is on)
 - T Contains a text file
 - C Changed time must be corrected
 - CNT Number of open file table entries for this inode.
 - DEV Major and minor device number of file system in which this inode resides.
 - INO I-number within the device.
 - MODE Mode bits, see *chmod*(S).
 - NLK Number of links to this inode.
 - UID User ID of owner.
 - SIZ/DEV Number of bytes in an ordinary file, or major and minor device of special file.
- x** Prints the text table with these headings:
 - LOC The core location of this table entry.
 - FLAGS Miscellaneous state variables encoded thus:
 - T *ptrace*(S) in effect
 - W Text not yet written on swap device
 - L Loading in progress

K Locked
 w Wanted (L flag is on)
 DADDR Disk address in swap, measured in multiples of BSIZE bytes.
 CADDR Core address, measured in units of memory management resolution.
 SIZE Size of text segment, measured in units of memory management resolution.
 IPTR Core location of corresponding inode.
 CNT Number of processes using this text segment.
 CCNT Number of processes in core using this text segment.

-p Prints process table for active processes with these headings:
 LOC The core location of this table entry.
 S Run state encoded thus:
 0 No process
 1 Waiting for some event
 3 Runnable
 4 Being created
 5 Being terminated
 6 Stopped under trace
 F Miscellaneous state variables, ORed together:
 01 Loaded
 02 The scheduler process
 04 Locked
 010 Swapped out
 020 Traced
 040 Used in tracing
 0100 Locked in by *lock*(S).
 PRI Scheduling priority, see *nice*(S).
 SIGNAL Signals received (signals 1-16 coded in bits 0-15).
 UID Real user ID.
 TIM Time resident in seconds; times over 127 coded as 127.
 CPU Weighted integral of CPU time, for scheduler.
 NI Nice level, see *nice*(S).
 PGRP Process number of root of process group (the opener of the controlling terminal).
 PID The process ID number.
 PPID The process ID of parent process.

ADDR If in core, the physical address of the "u-area" of the process measured in units of memory management resolution. If swapped out, the position in the swap area is measured in multiples of BSIZE bytes.

SIZE Size of process image, measured in units of memory management resolution.

WCHAN Wait channel number of a waiting process.

LINK Link pointer in list of runnable processes.

TEXTP If text is pure, pointer to location of text table entry.

CLKT Countdown for *alarm*(S) measured in seconds.

-u ubase

Print information about a user process. *Ubase* is the hexadecimal location of the process in main memory. The address may be obtained by using the long listing (**-l** option) of the *ps*(C) command.

-c corefile

Use the file *corefile* in place of */dev/kmem*.

-n namelist

Use the file *namelist* as an alternate namelist in place of */xenix*.

-f

Print the open file table with these headings:

LOC The core location of this table entry.

FLG Miscellaneous state variables:

R Open for reading

W Open for writing

P Pipe

CNT Number of processes that know this open file.

INO The location of the inode table entry for this file.

OFFS The file offset, see *lseek*(S).

Files

/xenix Namelist

/dev/mem Default source of tables

See Also

ps(C), *stat*(S), *filesystem*(F)

Name

pwadmin - Performs password aging administration.

Syntax

pwadmin [**-min weeks** **-max weeks**] options

Description

pwadmin is used to examine and modify the password aging information in the password file. The options one can specify are as follows:

-d user

Displays the password aging information.

-f user

Forces the user to change his password at the next login.

-c user

Prevents the user from changing his password.

-a user

Enables password aging for the given user. This option sets the minimum number of weeks that the user must wait before changing his password and the maximum number of weeks that a user can keep his current password for the values defined by the MINWEEKS and MAXWEEKS variables in the */etc/default/passwd* file. If the file is not found or the defined values are not in the range 0 to 63, the default values 2 and 4 are used.

-n user

Disables the password aging feature.

-min weeks

Enables password aging and sets the minimum number of weeks before the user can change his password to *weeks*. (This prevents him from changing his password back to the old one).

-max weeks

Enables password aging and sets the number of weeks so the user can keep his current password set for *weeks*.

Files

/etc/passwd

See Also

passwd(C), passwd(M)

Notes

The user must not attempt to force a new password by setting both the **-min** and **-max** values to zero. To force a password, use the **-f** option.

The user must not attempt to prevent further password changes by setting the **-min** value greater than the **-max** value. To prevent changes, use the **-c** option.

Name

`pwcheck` – Checks password file.

Syntax

`pwcheck [file]`

Description

pwcheck scans the password file and checks for any inconsistencies. The checks include validation of the number of fields, login name, user ID, group ID, and whether the login directory and optional program name exist. The default password file is */etc/passwd*.

Files

/etc/passwd

See Also

`grpcheck(C)`, `group(M)`, `passwd(M)`

Name

`pwd` – Prints working directory name.

Syntax

`pwd`

Description

pwd prints the pathname of the working (current) directory.

See Also

`cd`(C)

Diagnostics

“Cannot open ..” and “Read error in ..” indicate possible file system trouble. In such cases, see the *XENIX Operations Guide* for information on fixing the file system.

Name

quot – Summarizes file system ownership.

Syntax

quot [option] ... [filesystem]

Description

quot prints the number of blocks in the named *filesystem* currently owned by each user. If no *filesystem* is named, the file systems given in */etc/mnttab* are examined.

The following options are available:

- n Processes pipeline input for display. Specifically, the following pipeline:

```
ncheck filesystem | sort +0n | quot -n filesystem
```

produces a list of all files and their owners.

- c Prints three columns giving file size in blocks, number of files of that size, and cumulative total of blocks in that size or smaller file. Data for files of size greater than 499 blocks are included in the figures for files of exactly size 499.
- f Prints a count of the number of files as well as space owned by each user.

Files

<i>/etc/passwd</i>	Gets user names
<i>/etc/mnttab</i>	Contains list of mounted file systems

See Also

cmchk(C), du(C), ls(C), machine(M)

Notes

Holes in files are counted as if they actually occupied space.

Blocks are reported in 512 byte blocks. On filesystems that use 1024 byte blocks, a file of 26 bytes is reported as using 2 blocks, since it uses one 1024 byte block, or two 512 byte blocks. See *machine*(M) or use *cmchk*(C) to determine the filesystem block size.

See also *Notes* under *mount*(C).

Name

random – Generates a random number.

Syntax

random [**-s**] [*scale*]

Description

random generates a random number on the standard output, and returns the number as its exit value. By default, this number is either 0 or 1 (i.e., *scale* is 1 by default). If *scale* is given a value between 1 and 255, then the range of the random value is from 0 to *scale*. If *scale* is greater than 255, an error message is printed.

When the **-s** , “silent” option is given, the random number is returned as an exit value but is not printed on the standard output. If an error occurs, *random* returns an exit value of zero.

See Also

rand(S)

Notes

This command does not perform any floating point computations.

random uses the time of day as a seed.

Name

rcp – Copies files across XENIX systems.

Syntax

rcp [options] [srcmachine:]srcfile [destmachine:]destfile

Description

rcp copies files between systems in a Micnet network. The command copies the *srcmachine:srcfile* to *destmachine:destfile*, where *srcmachine:* and *destmachine:* are optional names of systems in the network, and *srcfile* and *destfile* are pathnames of files. If a machine name is not given, the name of the current system is assumed. If **-** is given in place of *srcfile*, *rcp* uses the standard input as the source. Directories named on the destination machine must have write permission, and directories and files named on a remote source machine must have read permission.

The available options are:

-m

Mails and reports completion of the command, whether there is an error or not.

-u [*machine:*]*user*

Any mail goes to the named *user* on *machine*. The default *machine* is the machine on which the *rcp* command is completed or on which an error was detected. If an alias for *user* exists in the system alias files on that *machine*, the mail will be redirected to the appropriate mailbox(es). Since system alias files are usually identical throughout the network, any specified *machine* will most likely be overridden by the aliasing mechanism. To prevent aliasing, *user* must be escaped with at least two \ characters (at least four if given as a shell command).

rcp is useful for transferring small numbers of files across the network. The network consists of daemons that periodically awaken and send files from one system to another. The network must be installed using *netutil* (C) before *rcp* can be used.

Also, to enable transfer of files from a remote system, either:

This line should be in */etc/default/micnet* on the systems in the network:

```
rcp=/usr/bin/rcp
```

Or, these lines should be in that file:

```
executeall  
execpath=PATH=path
```

where *path* must contain */usr/bin*.

Example

```
rcp -m machine1:/etc/mnttab /tmp/vtape
```

See Also

mail(C), micnet(M), netutil(C), remote(C)

Diagnostics

If an error occurs, mail is sent to the user.

Notes

Full pathnames must be specified for remote files.

rcp handles binary data files transparently, no extra options or protocols are needed to handle them. Wildcards are not expanded on the remote machine.

Name

red – Invokes a restricted version of *ed*(C).

Syntax

red [file]

Description

red is a restricted version of *ed*(C). It will only allow editing of files in the current directory. It prohibits executing *sh*(C) commands via the *!* command. *red* displays an error message on any attempt to bypass these restrictions.

In general, *red* does not allow commands like

!date

or

!sh

Furthermore, *red* will not allow pathnames in its command line. For example, the command:

red /etc/passwd

when the current directory is not */etc* causes an error.

See Also

ed(C), *rsh*(C)

Name

`remote` - Executes commands on a remote XENIX system.

Syntax

```
remote [ - ] [ -f file ] [ -m ] [ -u user ] machine  
command [ arguments ]
```

Description

remote is a limited networking facility that permits execution of XENIX commands across serial lines. Commands on any connected system may be executed from the host system using *remote*. A command line consisting of *command* and any blank-separated *arguments* is executed on the remote *machine*. A machine's name is located in the file `/etc/systemid`. Note that wild cards are *not* expanded on the remote machine, so they should not be specified in *arguments*. The optional `-m` switch causes mail to be sent to the user telling whether the command is successful.

The available options follow:

- `-` A dash signifies that standard input is used as the standard input for *command* on the remote *machine*. Standard input comes from the local host and not from the remote machine.
- `-f file` Use the specified *file* as the standard input for *command* on the remote *machine*. The *file* exists on the local host and not on the remote machine.
- `-m` Mails the user to report completion of the command. By default, mail reports only errors.
- `-u user` Any mail goes to the named *user* on *machine*. The default *machine* is the machine on which an error was detected, or on which the *remote* command was completed. The mail will be redirected to the appropriate mailbox(es), if an alias for *user* exists in the system alias files on that *machine*. Since system alias files are usually identical throughout the network, any specified *machine* will most likely be overridden by the aliasing mechanism. To prevent aliasing, *user* must be escaped with at least two `\` characters (at least four if given as a shell command).

Before *remote* can be successfully used, a network of systems must first be set up and the proper daemons initialized using *netutil* (C). Also, entries for the command to be executed using *remote* must be added to the */etc/default/micnet* files on each remote machine.

Example

The following command executes an *ls* command on the directory */tmp* of the machine *machine1*:

```
remote machine1 ls /tmp
```

See Also

rcp(C), mail(C), netutil(C), micnet(M)

Notes

The *mail* command uses the equivalent of *remote* to send mail between machines.

Name

restore, restor – Invokes incremental file system restorer.

Syntax

restore key [arguments]

restor key [arguments]

Description

restore is used to read archive media backed up with the *backup(C)* command. The *key* specifies what is to be done. *Key* is one of the characters *cC*, *rR*, *tT*, or *xX* optionally combined with *k* and/or *f* or *F*. *restor* is an alternate spelling for the same command.

c,C

Verify (check) a dump tape. Used after a dump is made to make sure the tape has no I/O errors or bad checksums. *C* is the same as *c* except that it provides a higher level of checking.

f Uses the first *argument* as the name of the archive (backup device /dev/*) instead of the default.

F *F* is the number of the first file on the tape to read. All files up to that point are skipped.

k Follow this option with the size of the backup volume. This allows for reading multivolume dumps from media such as floppies.

r,R

The archive is read and loaded into the file system specified in *argument*. This should not be done lightly (see below). If the key is *R*, *restore* asks which archive of a multivolume set to start on. This allows *restore* to be interrupted and then restarted (an *fsck* must be done before the restart).

t Prints the date the archive was written and the date the file system was backed up.

T Prints a full listing of a dump tape. Similar to *t*.

x Each file on the archive named by an *argument* is extracted. The filename has all "mount" prefixes removed; for example, if /usr is a mounted file system, /usr/bin/lpr is named /bin/lpr on the archive.

The extracted file is placed in a file with a numeric name supplied by *restore* (actually the inode number). In order to keep the amount of archive read to a minimum, the following procedure is recommended:

1. Mount volume 1 of the set of backup archives.
2. Type the *restore* command with the appropriate key and arguments.
3. *restore* will check *dumpdir*, then announce whether or not it found the files, give the numeric name that it will assign to the file, and in the case of a tape, rewind to the start of the archive.
4. It then asks you to "mount the desired tape volume". Type the number of the volume you choose. On a multivolume backup, the recommended procedure is to mount the last through the first volumes, in that order. *restore* checks to see if any of the requested files are on the mounted archive (or a later archive, thus the reverse order). If the requested files are not there, *restore* doesn't read through the tape. If you are working with a single-volume backup or if the number of files being restored is large, respond to the query with 1 and *restore* will read the archives in sequential order.

X Same as x except that files are replaced in original location.

The r option should only be used to restore a complete backup archive onto a clear file system, or to restore an incremental backup archive onto a file system so created. Thus:

```
/etc/mkfs /dev/hd1 10000
restore r /dev/hd1
```

is a typical sequence to restore a complete backup. Another *restore* can be done to get an incremental backup in on top of this.

A *backup* followed by a *mkfs* and a *restore* is used to change the size of a file system.

Files

rst*	Temporary files
/etc/default/restor	Name of default archive device

The default archive unit varies with installation.

Notes

It is not possible to successfully *restore* an entire active root file system.

Diagnostics

There are various diagnostics involved with reading the archive and writing the disk. There are also diagnostics if the i-list or the free list of the file system is not large enough to hold the dump.

If the dump extends over more than one disk or tape, *restor* may ask you to change disks or tapes. Reply with a newline when the next unit has been mounted.

See Also

backup(C), dumpdir(C), fsck(C), mkfs(C), sddate(C)

Name

rm, rmdir - Removes files or directories.

Syntax

rm [**-fri**] file ...

rmdir dir ...

Description

rm removes the entries for one or more files from a directory. If an entry was the last link to the file, the file is destroyed. Removal of a file requires write permission in its directory, but neither read nor write permission on the file itself.

If a file has no write permission and the standard input is a terminal, its permissions are printed and a line is read from the standard input. If that line begins with **y**, the file is deleted, otherwise the file remains. No questions are asked when the **-f** option is given or if the standard input is not a terminal.

If a designated file is a directory, an error comment is printed unless the optional argument **-r** has been used. In that case, **rm** recursively deletes the entire contents of the specified directory, and the directory itself.

If the **-i** (interactive) option is in effect, **rm** asks whether to delete each file, and if the **-r** option is in effect, whether to examine each directory.

rmdir removes empty directories.

See Also

rmdir(C)

Diagnostics

Generally self-explanatory. It is forbidden to remove the file **..** to avoid the consequences of inadvertently doing something like:

```
rm -r .*
```

It is also forbidden to remove the root directory of a given file system.

No more than 17 levels of subdirectories can be removed using the
-r option.

Name

rmdir – Removes directories.

Syntax

rmdir dir ...

Description

rmdir removes the entries for one or more subdirectories from a directory. A directory must be empty before it can be removed. *rmdir* enforces a standard and *safe* procedure for removing a directory; the contents of the directory must be removed before the directory itself can be deleted with *rmdir*. Note that the “*rm -r dir*” command is a more dangerous alternative to *rmdir*.

rmdir removes entries for the named directories, which must be empty.

See Also

rm(C)

Notes

rmdir will refuse to remove the root directory of a mounted file system.

Name

rmuser – Removes a user from the system.

Syntax

/etc/rmuser

Description

rmuser removes users from the system. It begins by prompting for a user name; after receiving a valid user name as a response, it then deletes the named user's entry in the password file, and removes the user's mailbox file, the *.profile* file, and the entire home directory. It will also remove the users group entry in */etc/group* if the user was the only remaining member of that group, and the group ID was greater than 50.

Before removing a user ID from the system, make sure its mailbox is empty and that all files belonging to that user ID have been saved or deleted as required.

The *rmuser* program will refuse to remove a user ID or any of its files if one or more of the following checks fails:

- The user name given is one of the "system" user names such as root, sys, sysinfo, cron, or uucp. All user IDs less than 200 are considered reserved for system use, and cannot be removed using *rmuser*. Likewise, all group IDs less than 50 are not removable using *rmuser*.
- The user's mailbox exists and is not empty.
- The user's home directory contains files other than *.profile*.

rmuser can only be executed by the super-user.

Files

/etc/passwd

/usr/spool/mail/username

\$HOME

See Also

mkuser(C), *backup(C)*

Name

`rsh` - Invokes a restricted shell (command interpreter).

Syntax

`rsh [flags] [name [arg1 ...]]`

Description

`rsh` is a restricted version of the standard command interpreter `sh`(C). It is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. The actions of `rsh` are identical to those of `sh`, except that changing directory with `cd`, setting the value of `$PATH`, using command names containing slashes, and redirecting output using `>` and `>>` are all disallowed.

When invoked with the name `-rsh`, `rsh` reads the user's `.profile` (from `$HOME/.profile`). It acts as the standard `sh` while doing this, except that an interrupt causes an immediate exit, instead of causing a return to command level. The restrictions above are enforced after `.profile` is interpreted.

When a command to be executed is found to be a shell procedure, `rsh` invokes `sh` to execute it. Thus, it is possible to provide to the end user shell procedures that have access to the full power of the standard shell, while restricting him to a limited menu of commands; this scheme assumes that the end user does not have write and execute permissions in the same directory.

The net effect of these rules is that the writer of the `.profile` has complete control over user actions, by performing guaranteed setup actions, then leaving the user in an appropriate directory (probably *not* the login directory).

`rsh` is actually just a link to `sh` and any *flags* arguments are the same as for `sh`(C).

The system administrator often sets up a directory of commands that can be safely invoked by `rsh`.

See Also

`sh`(C), `profile`(M)

Name

runbig - Runs a command that may require more memory than normal.

Syntax

runbig command [arguments]

Description

runbig executes commands that may require more memory than is normally available to a user process. While *runbig* is executing the specified *command*, it ignores the restriction on the default of memory available to the user process. The *command* will run normally until it grows to be larger than the amount of memory available to a user process. It is then locked in core memory and not swapped until it either exits or shrinks to a size less than or equal to the size of a default user process.

The removal of the process size restriction during execution of *runbig* will be preserved during an *exec*(S) system call, but not for a *fork*(S) system call.

See Also

exec(S), fork(S)

Notes

Running programs greater than the default process size, and therefore, possibly greater than the size of the disk swap area, may severely impact system performance.

runbig has no effect on systems whose memory size is much less than the size of the disk swap area.

Name

sddate - Prints and sets backup dates.

Syntax

sddate [name lev date]

Description

If no argument is given, the contents of the backup date file */etc/ddate* are printed. The backup date file is maintained by *backup(C)* and contains the date of the most recent backup for each backup level for each filesystem.

If arguments are given, an entry is replaced or made in */etc/ddate*. *name* is the last component of the device pathname, *lev* is the backup level number (from 0 to 9), and *date* is a time in the form taken by *date(C)*:

mmddhhmm[yy]

Where the first *mm* is a two-digit month in the range 01-12, *dd* is a two-digit day of the month, *hh* is a two-digit military hour from 00-23, and the final *mm* is a two-digit minute from 00-59. An optional two-digit year, *yy*, is presumed to be an offset from the year 1900, i.e., 19yy.

Some sites may wish to back up file systems by copying them verbatim to backup media. *sddate* could be used to make a "level 0" entry in */etc/ddate*, which would then allow incremental backups.

For example:

sddate rhd0 5 10081520

makes an */etc/ddate* entry showing a level 5 backup of */dev/rhd0* on October 8, at 3:20 PM.

Files

/etc/ddate

SDDATE (C)

SDDATE (C)

See Also

backup(C), dump(C), date(C)

Diagnostics

bad conversion If the date set is syntactically incorrect.

Name

sdiff – Compares files side-by-side.

Syntax

sdiff [options ...] file1 file2

Description

sdiff uses the output of *diff*(C) to produce a side-by-side listing of two files indicating those lines that are different. Each line of the two files is printed with a blank gutter between them if the lines are identical, a < in the gutter if the line only exists in *file1*, a > in the gutter if the line only exists in *file2*, and a | for lines that are different.

For example:

x		y
a		a
b	<	
c	<	
d		d
	>	c

The following options exist:

- w *n*** Uses the next argument, *n*, as the width of the output line. The default line length is 130 characters.
- l** Only prints the left side of any lines that are identical.
- s** Does not print identical lines.
- o *output*** Uses the next argument, *output*, as the name of a third file that is created as a user-controlled merging of *file1* and *file2*. Identical lines of *file1* and *file2* are copied to *output*. Sets of differences, as produced by *diff*(C), are printed; where a set of differences share a common gutter character. After printing each set of differences, *sdiff* prompts the user with a % and waits for one of the following user-typed commands:

- l** Appends the left column to the output file
- r** Appends the right column to the output file

- s** Turns on silent mode; does not print identical lines
- v** Turns off silent mode
- e l**
Calls the editor with the left column
- e r**
Calls the editor with the right column
- e b**
Calls the editor with the concatenation of left and right
- e** Calls the editor with a zero length file
- q** Exits from the program

On exit from the editor, the resulting file is concatenated on the end of the *output* file.

See Also

diff(C), ed(C)

Name

`sed` – Invokes the stream editor.

Syntax

`sed [-n] [-e script] [-f sfile] [files]`

Description

`sed` copies the named *files* (standard input default) to the standard output, edited according to a script of commands. The `-f` option causes the script to be taken from file *sfile*; these options accumulate. If there is just one `-e` option and no `-f` options, the flag `-e` may be omitted. The `-n` option suppresses the default output. A script consists of editing commands, one per line, of the following form:

[address [, address]] function [arguments]

In normal operation, `sed` cyclically copies a line of input into a *pattern space* (unless there is something left after a D command), applies in sequence all commands whose *addresses* select that pattern space, and at the end of the script copies the pattern space to the standard output (except under `-n`) and deletes the pattern space.

Some of the commands use a *hold space* to save all or part of the *pattern space* for subsequent retrieval.

An *address* is either a decimal number that counts input lines cumulatively across files, a \$ that addresses the last line of input, or a context address, i.e., a */regular expression/* in the style of `ed(C)` modified as follows:

- In a context address, the construction `\?regular expression?`, where `?` is any character, is identical to `/regular expression/`. Note that in the context address `\abc\xdefx`, the second `x` stands for itself, so that the regular expression is `abcxdef`.
- The escape sequence `\n` matches a newline *embedded* in the pattern space.
- A period `.` matches any character except the *terminal* newline of the pattern space.
- A command line with no addresses selects every pattern space.

- A command line with one address selects each pattern space that matches the address.
- A command line with two addresses selects the inclusive range from the first pattern space that matches the first address through the next pattern space that matches the second. (If the second address is a number less than or equal to the line number first selected, only one line is selected.) Thereafter, the process is repeated, looking again for the first address.

Editing commands can be applied only to nonselected pattern spaces by use of the negation function ! (below).

In the following list of functions, the maximum number of permissible addresses for each function is indicated in parentheses.

The *text* argument consists of one or more lines, all but the last of which end with backslashes to hide the newlines. Backslashes in text are treated like backslashes in the replacement string of an *s* command, and may be used to protect initial blanks and tabs against the stripping that is done on every script line. The *rfile* or *wfile* argument must terminate the command line and must be preceded by exactly one blank. Each *wfile* is created before processing begins. There can be at most 10 distinct *wfile* arguments.

(1) **a**

text Appends *text*, placing it on the output before reading the next input line.

(2) **b label** Branches to the : command bearing the *label*. If *label* is empty, branches to the end of the script.

(2) **c**

text Changes text by deleting the pattern space and then appending *text*. With 0 or 1 address or at the end of a 2-address range, places *text* on the output and starts the next cycle.

(2) **d** Deletes the pattern space and starts the next cycle.

(2) **D** Deletes the initial segment of the pattern space through the first newline and starts the next cycle.

(2) **g** Replaces the contents of the pattern space with the contents of the hold space.

(2) **G** Appends the contents of the hold space to the pattern space.

(2) **h** Replaces the contents of the hold space with the contents of the pattern space.

- (2) **H** Appends the contents of the pattern space to the hold space.
- (1) **i**
text Insert. Places *text* on the standard output.
- (2) **l** Lists the pattern space on the standard output with non-printing characters spelled in two-digit ASCII and long lines folded.
- (2) **n** Copies the pattern space to the standard output. Replaces the pattern space with the next line of input.
- (2) **N** Appends the next line of input to the pattern space with an embedded newline. (The current line number changes.)
- (2) **p** Prints (copies) the pattern space on the standard output.
- (2) **P** Prints (copies) the initial segment of the pattern space through the first newline to the standard output.
- (1) **q** Quits *sed* by branching to the end of the script. No new cycle is started.
- (2) **r** *rfile* Reads the contents of *rfile* and places them on the output before reading the next input line.
- (2) **s**/*regular expression/replacement/flags*
Substitutes the *replacement* string for instances of the *regular expression* in the pattern space. Any character may be used instead of */*. For a more detailed description, see *ed*(C). *Flags* is zero or more of:
 - g** Globally substitutes for all nonoverlapping instances of the *regular expression* rather than just the first one.
 - p** Prints the pattern space if a replacement was made.
 - w** *wfile*
Writes the pattern space to *wfile* if a replacement was made.
- (2) **t** *label* Branches to the colon (:) command bearing *label* if any substitutions have been made since the most recent reading of an input line or execution of a **t** command. If *label* is empty, **t** branches to the end of the script.
- (2) **w** *wfile* Writes the pattern space to *wfile*.

- (2) **x** Exchanges the contents of the pattern and hold spaces.
- (2) **y/string1/string2/**
Replaces all occurrences of characters in *string1* with the corresponding characters in *string2*. The lengths of *string1* and *string2* must be equal.
- (2) **! function**
Applies the *function* (or group, if *function* is { }) only to lines *not* selected by the address(es).
- (0) **: label** This command does nothing; it bears a *label* for **b** and **t** commands to branch to.
- (1) **=** Places the current line number on the standard output as a line.
- (2) **{** Executes the following commands through a matching **}** only when the pattern space is selected.
- (0) An empty command is ignored.

See Also

awk(C), ed(C), grep(C)
The *XENIX Text Processing Guide*

Notes

This command is explained in detail in *XENIX Text Processing Guide*.

Name

setcolor – Set screen color.

Syntax

setcolor – [nbrg] color [color]

Description

setcolor allows the user to set the screen color on the color monitor. Both foreground and background colors can be set independently in a range of 16 colors. **setcolor** can also set the reverse video and graphics character colors. **setcolor** with no arguments produces a usage message that displays all available colors, then resets the screen to its previous state.

For example, the following strings are possible colors. (Colors on your particular machine may be different.)

blue	magenta	brown	black
lt_blue	lt_magenta	yellow	gray
cyan	white	lt_green	red
lt_cyan	hi_white	green	lt_red

The following flags are available. In the arguments below, “color” is taken from the above list.

-n

Set the screen to “normal” white characters on black background.

color [color]

Set the foreground to the first color. Sets background to second color if a second color choice is specified.

-b color

Set the background to the specified color.

-r color color

Set the foreground reverse video characters to the first color. Set reverse video characters’ background to second color.

-g color color

Set the foreground graphics characters to the first color. Set graphics characters’ background to second color.

Notes

Occasionally changing the screen color can help prolong the life of your monitor.

setcolor has no effect on monochrome monitors.

See Also

`console(M)`

Name

setmnt – Establishes /etc/mnttab table.

Syntax

/etc/setmnt

Description

setmnt creates the **/etc/mnttab** table (see *mnttab*(F)), which is needed for both the *mount*(C) and *umount*(C) commands. *setmnt* reads the standard input and creates a *mnttab* entry for each line. Input lines have the format:

filesys node

where *filesys* is the name of the file system's *special file* (e.g., "hd0") and *node* is the root name of that file system. Thus *filesys* and *node* become the first two strings in the *mnttab*(F) entry.

Files

/etc/mnttab

See Also

mnttab(F)

Notes

If *filesys* or *node* are longer than 128 characters, errors can occur.

setmnt silently enforces an upper limit on the maximum number of *mnttab* entries.

setmnt is normally invoked by **/etc/rc** when the system boots up.

Name

settime – Changes the access and modification dates of files.

Syntax

settime mmddhhmm [yy] [-f fname] name ...

Description

Sets the access and modification dates for one or more files. The dates are set to the specified date, or to the access and modification dates of the file specified via **-f**. Exactly one of these methods must be used to specify the new date(s). The first *mm* is the month number; *dd* is the day number in the month; *hh* is the hour number (24 hour system); the second *mm* is the minute number; *yy* is the last two digits of the year and is optional. For example:

```
settime 1008004583 ralph pete
```

sets the access and modification dates of files *ralph* and *pete* to Oct 8, 12:45 AM, 1983. Another example:

```
settime -f ralph john
```

This sets the access and modification dates of the file *john* to those of the file *ralph*.

Notes

Use of *touch* in place of *settime* is encouraged.

Name

sh - Invokes the shell command interpreter.

Syntax

sh [**-ceiknrstuvx**] [args]

Description

The shell is the standard command programming language that executes commands read from a terminal or a file. See *Invocation* below for the meaning of arguments to the shell.

Commands

A *simple-command* is a sequence of nonblank *words* separated by *blanks* (a *blank* is a tab or a space). The first word specifies the name of the command to be executed. Except as specified below, the remaining words are passed as arguments to the invoked command. The command name is passed as argument 0 (see *exec(S)*). The *value* of a simple-command is its exit status if it terminates normally, or (octal) 1000+*status* if it terminates abnormally (i.e., if the failure produces a core file). See *signal(S)* for a list of status values.

A *pipeline* is a sequence of one or more *commands* separated by a vertical bar (`|`). (The caret (`^`), also has the same effect.) The standard output of each command but the last is connected by a *pipe(S)* to the standard input of the next command. Each command is run as a separate process; the shell waits for the last command to terminate.

A *list* is a sequence of one or more pipelines separated by `;`, `&`, `&&`, or `||`, and optionally terminated by `;` or `&`. Of these four symbols, `;` and `&` have equal precedence, which is lower than that of `&&` and `||`. The symbols `&&` and `||` also have equal precedence. A semicolon (`;`) causes sequential execution of the preceding pipeline; an ampersand (`&`) causes asynchronous execution of the preceding pipeline (i.e., the shell does *not* wait for that pipeline to finish). The symbol `&&` (`||`) causes the *list* following it to be executed only if the preceding pipeline returns a zero (nonzero) exit status. An arbitrary number of newlines may appear in a *list*, instead of semicolons, to delimit commands.

A *command* is either a simple-command or one of the following commands. Unless otherwise stated, the value returned by a command is that of the last simple-command executed in the command:

for name [in word ...] do list done

Each time a **for** command is executed, *name* is set to the next *word* taken from the **in word** list. If **in word** is omitted, then the **for** command executes the **do list** once for each positional parameter that is set (see *Parameter Substitution* below). Execution ends when there are no more words in the list.

case word in [pattern [|pattern] ...) list ;;] ... esac

A **case** command executes the *list* associated with the first *pattern* that matches *word*. The form of the patterns is the same as that used for filename generation (see *Filename Generation* below).

if list then list [elif list then list] ... [else list] fi

The *list* following **if** is executed and, if it returns a zero exit status, the *list* following the first **then** is executed. Otherwise, the *list* following **elif** is executed and, if its value is zero, the *list* following the next **then** is executed. Failing that, the **else list** is executed. If no **else list** or **then list** is executed, then the **if** command returns a zero exit status.

while list do list done

A **while** command repeatedly executes the **while list** and, if the exit status of the last command in the list is zero, executes the **do list**; otherwise the loop terminates. If no commands in the **do list** are executed, then the **while** command returns a zero exit status; **until** may be used in place of **while** to negate the loop termination test.

(list)

Executes *list* in a subshell.

{list;}

list is simply executed.

name () {list;}

Define a function which is referenced by *name*. The body of functions is the *list* of commands between **{** and **}**. Execution of functions is described below (see *Execution*.)

The following words are recognized only as the first word of a command and when not quoted:

if then else elif fi case esac for while until do done { }

Comments

A word beginning with `#` causes that word and all the following characters up to a newline to be ignored.

Command Substitution

The standard output from a command enclosed in a pair of grave accents (```) may be used as part or all of a word; trailing newlines are removed.

Parameter Substitution

The character `$` is used to introduce substitutable *parameters*. Positional parameters may be assigned values by `set`. Variables may be set by writing:

```
name=value [ name=value ] . . .
```

Pattern-matching is not performed on *value*.

`${parameter}`

A *parameter* is a sequence of letters, digits, or underscores (a *name*), a digit, or any of the characters `*`, `@`, `#`, `?`, `-`, `$`, and `!`. The value, if any, of the parameter is substituted. The braces are required only when *parameter* is followed by a letter, digit, or underscore that is not to be interpreted as part of its name. A *name* must begin with a letter or underscore. If *parameter* is a digit then it is a positional parameter. If *parameter* is `*` or `@`, then all the positional parameters, starting with `$1`, are substituted (separated by spaces). Parameter `$0` is set from argument zero when the shell is invoked.

`${parameter:-word}`

If *parameter* is set and is not a null argument, substitute its value; otherwise substitute *word*.

`${parameter:=word}`

If *parameter* is not set or is null, then set it to *word*; the value of the parameter is then substituted. Positional parameters may not be assigned to in this way.

`${parameter:?word}`

If *parameter* is set and is not a null argument, substitute its value; otherwise, print *word* and exit from the shell. If *word* is omitted, the message "parameter null or not set" is printed.

\${parameter:+word}

If *parameter* is set and is not a null argument, substitute *word*; otherwise substitute nothing. In the above, *word* is not evaluated unless it is to be used as the substituted string, so that in the following example, **pwd** is executed only if **d** is not set or is null:

```
echo ${d:-`pwd`}
```

If the colon (:) is omitted from the above expressions, then the shell only checks whether *parameter* is set.

The following parameters are automatically set by the shell:

- #** The number of positional parameters in decimal
- Flags supplied to the shell on invocation or by the **set** command
- ?** The decimal value returned by the last synchronously executed command
- \$** The process number of this shell
- !** The process number of the last background command invoked

The following parameters are used by the shell:

HOME

The default argument (home directory) for the **cd** command

PATH

The search path for commands (see *Execution* below)

MAIL

If this variable is set to the name of a mail file, then the shell informs the user of the arrival of mail in the specified file

MAILCHECK

This parameter specifies how often (in seconds) the shell will check for the arrival of mail in the files specified by the **MAILPATH** or **MAIL** parameters. The default value is 600 seconds (10 minutes). If set to 0, the shell will check before each prompt.

MAILPATH

A colon (:) separated list of file names. If this parameter is set, the shell informs the user of the arrival of mail in any of the specified files. Each file name can be followed by % and a message that will be printed when the modification time changes. The default message is *you have mail*.

PS1

Primary prompt string, by default "\$ "

PS2

Secondary prompt string, by default "> "

IFS

Internal field separators, normally **space**, **tab**, and **newline**

SHACCT

If this parameter is set to the name of a file writable by the user, the shell will write an accounting record in the file for each shell procedure executed. Accounting routines such as *acctcom*(C) and *accton*(C) can be used to analyze the data collected.

SHELL

When the shell is invoked, it scans the environment (see *Environment* below) for this name. If it is found and there is an 'r' in the file name part of its value, the shell becomes a restricted shell.

The shell gives default values to **PATH**, **PS1**, **PS2**, and **IFS**, while **HOME** and **MAIL** are not set at all by the shell (although **HOME** is set by *login*(M)).

Blank Interpretation

After parameter and command substitution, the results of substitution are scanned for internal field separator characters (those found in **IFS**) and split into distinct arguments where such characters are found. Explicit null arguments (" or '') are retained. Implicit null arguments (those resulting from *parameters* that have no values) are removed.

Filename Generation

Following substitution, each command *word* is scanned for the characters *, ?, and [. If one of these characters appears, the word is regarded as a *pattern*. The word is replaced with alphabetically sorted filenames that match the pattern. If no filename is found that matches the pattern, the word is left unchanged. The character . at the start of a filename or immediately following a /, as well as the character / itself, must be matched explicitly. These characters and their matching patterns are:

- * Matches any string, including the null string.
- ? Matches any single character.

[...]

Matches any one of the enclosed characters. A pair of characters separated by - matches any character lexically between the pair, inclusive. If the first character following the opening bracket ([]) is an exclamation mark (!), then any character not enclosed is matched.

Quoting

The following characters have a special meaning to the shell and cause termination of a word unless quoted:

; & () | ^ < > newline space tab

A character may be *quoted* (i.e., made to stand for itself) by preceding it with a \. The pair \newline is ignored. All characters enclosed between a pair of single quotation marks (''), except a single quotation mark, are quoted. Inside double quotation marks (""), parameter and command substitution occurs and \ quotes the characters \, \, ", and \$. "\$*" is equivalent to "\$1 \$2 ...", whereas "\$@" is equivalent to "\$1" "\$2" ...

Prompting

When used interactively, the shell prompts with the value of PS1 before reading a command. If at any time a newline is typed and further input is needed to complete a command, the secondary prompt (i.e., the value of PS2) is issued.

Spelling Checker

When using cd(C) the shell checks spelling. For example, if you change to a different directory using cd and misspell the directory name, the shell responds with an alternative spelling of an existing directory. Enter "y" and press RETURN to change to the offered directory, or retype the command line if the offered spelling is incorrect. In this example the sh(C) response is **boldfaced**.

```
$ cd /usr/spol/uucp
cd /usr/spool/uucp?y
ok
```

Input/Output

Before a command is executed, its input and output may be redirected using a special notation interpreted by the shell. The following may appear anywhere in a simple-command or may precede or follow a *command*. They are *not* passed on to the invoked command; substitution occurs before *word* or *digit* is used:

- <word** Use file *word* as standard input (file descriptor 0).
- >word** Use file *word* as standard output (file descriptor 1). If the file does not exist, it is created; otherwise, it is truncated to zero length.
- >>word** Use file *word* as standard output. If the file exists, output is appended to it (by first seeking the end-of-file); otherwise, the file is created.
- <<[-]word** The shell input is read up to a line that is the same as *word*, or to an end-of-file. The resulting document becomes the standard input. If any character of *word* is quoted, no interpretation is placed upon the characters of the document; otherwise, parameter and command substitution occurs, (unescaped) **\newline** is ignored, and **** must be used to quote the characters ****, **\$**, **^**, and the first character of *word*. If **-** is appended to **<<**, all leading tabs are stripped from *word* and from the document.
- <&digit** The standard input is duplicated from file descriptor *digit* (see *dup(S)*). Similarly for the standard output using **>**.
- <&-** The standard input is closed. Similarly for the standard output using **>**.

If one of the above is preceded by a digit, the file descriptor created is that specified by the digit (instead of the default 0 or 1). For example:

```
... 2>&1
```

creates file descriptor 2 that is a duplicate of file descriptor 1.

If a command is followed by **&**, the default standard input for the command is the empty file **/dev/null**. Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input/output specifications.

Environment

The *environment* (see *environ(M)*) is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a parameter for each name found, giving it the corresponding value. Executed commands inherit the same environment. If the user modifies the values of these parameters or creates new ones, none of these affect the environment unless the **export** command is used

to bind the shell's parameter to the environment. The environment seen by any executed command is composed of any unmodified name-value pairs originally inherited by the shell, minus any pairs removed by **unset**, plus any modifications or additions, all of which must be noted in **export** commands.

The environment for any *simple-command* may be augmented by prefixing it with one or more assignments to parameters. Thus:

```
TERM=450 cmd args
```

and

```
(export TERM; TERM=450; cmd args)
```

are equivalent (as far as the above execution of *cmd* is concerned).

If the **-k** flag is set, *all* keyword arguments are placed in the environment, even if they occur after the command name.

Signals

The **INTERRUPT** and **QUIT** signals for an invoked command are ignored if the command is followed by **&**; otherwise signals have the values inherited by the shell from its parent, with the exception of signal 11. See the **trap** command below.

Execution

Each time a command is executed, the above substitutions are carried out. Except for the *Special Commands* listed below, a new process is created and an attempt is made to execute the command via *exec(S)*.

The shell parameter **PATH** defines the search path for the directory containing the command. Alternative directory names are separated by a colon (:). The default path is **:/bin:/usr/bin** (specifying the current directory, **/bin**, and **/usr/bin**, in that order). Note that the current directory is specified by a null pathname, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If the command name contains a **/**, then the search path is not used. Otherwise, each directory in the path is searched for an executable file. If the file has execute permission but is not an **a.out** file, it is assumed to be a file containing shell commands. A subshell (i.e., a separate process) is spawned to read it. A parenthesized command is also executed in a subshell.

Shell procedures are often used by users running the **cs**h . However, if the first character of the procedure is a # (comment character), the **cs**h assumes the procedure is a **cs**h script, and invokes */bin/csh* to execute it. Always start **sh** procedures with some other character if **cs**h users are to run the procedure at any time. This invokes the standard shell */bin/sh* .

The location in the search path where a command was found is remembered by the shell (to help avoid unnecessary *execs* later). If the command was found in a relative directory, its location must be re-determined whenever the current directory changes. The shell forgets all remembered locations whenever the **PATH** variable is changed or the **hash -r** command is executed (see below).

Special Commands

Input/output redirection is now permitted for these commands:

: No effect; the command does nothing. A zero exit code is returned.

. *file*

Reads and executes commands from *file* and returns. The search path specified by **PATH** is used to find the directory containing *file*.

break [*n*]

Exits from the enclosing **for** or **while** loop, if any. If *n* is specified, it breaks *n* levels.

continue [*n*]

Resumes the next iteration of the enclosing **for** or **while** loop. If *n* is specified, it resumes at the *n*-th enclosing loop.

cd [*arg*]

Changes the current directory to *arg*. The shell parameter **HOME** is the default *arg*. The shell parameter **CDPATH** defines the search path for the directory containing *arg*. Alternative directory names are separated by a colon (:). The default path is <null> (specifying the current directory). Note that the current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If *arg* begins with a /, the search path is not used. Otherwise, each directory in the path is searched for *arg*.

If the shell is reading its commands from a terminal, and the specified directory does not exist (or some component cannot be searched), spelling correction is applied to each component of *directory*, in a search for the "correct" name. The shell then asks whether or not to try and change directory to the corrected directory name; an answer of *n* means "no", and anything else is taken as "yes".

eval [*arg* ...]

The arguments are read as input to the shell and the resulting command(s) executed.

exec [*arg* ...]

The command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and, if no other arguments are given, cause the shell input/output to be modified.

exit [*n*]

Causes a shell to exit with the exit status specified by *n*. If *n* is omitted, the exit status is that of the last command executed. An end-of-file will also cause the shell to exit.

export [*name* ...]

The given *names* are marked for automatic export to the *environment* of subsequently executed commands. If no arguments are given, a list of all names that are exported in this shell is printed.

hash [**-r**] [*name* ...]

For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The **-r** option causes the shell to forget all remembered locations. If no arguments are given, information about remembered commands is presented. *Hits* is the number of times a command has been invoked by the shell process. *Cost* is a measure of the work required to locate a command in the search path. There are certain situations which require that the stored location of a command be recalculated. Commands for which this will be done are indicated by an asterisk (*) adjacent to the *hits* information. *Cost* will be incremented when the recalculation is done.

newgrp [*arg* ...]

Equivalent to **exec newgrp** *arg* ...

pwd

Print the current working directory. See *pwd*(C) for usage and description.

read [*name* ...]

One line is read from the standard input and the first word is assigned to the first *name*, the second word to the second *name*, etc., with leftover words assigned to the last *name*. The return code is 0 unless an end-of-file is encountered.

readonly [*name* ...]

The given *names* are marked *readonly* and the values of these *names* may not be changed by subsequent assignment. If no arguments are given, a list of all *readonly* names is printed.

return [*n*]

Causes a function to exit with the return value specified by *n*. If *n* is omitted, the return status is that of the last command executed.

set [**-eknuvx** [*arg* ...]]**-e**

If the shell is noninteractive, exits immediately if a command exits with a nonzero exit status.

-f Disables file name generation.**-h**

Locates and remembers function commands as function are defined (function commands are normally located when the function is executed).

-k

Places all keyword arguments in the environment for a command, not just those that precede the command name.

-n

Reads commands but does not execute them.

-u

Treats unset variables as an error when substituting.

-v

Prints shell input lines as they are read.

-x

Prints commands and their arguments as they are executed. Although this flag is passed to subshells, it does not enable tracing in those subshells.

--

Does not change any of the flags; useful in setting \$1 to -.

Using **+** rather than **-** causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in **\$-**. The remaining arguments are positional parameters and are assigned, in order, to **\$1**, **\$2**, ... If no arguments are given, the values of all names are printed.

shift

The positional parameters from **\$2** ... are renamed **\$1** ...

test

Evaluates conditional expressions. See *test*(C) for usage and description.

times

Prints the accumulated user and system times for processes run from the shell.

trap [*arg*] [*n*] ...

arg is a command to be read and executed when the shell receives signal(s) *n*. (Note that *arg* is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number. The highest signal number allowed is 16. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If *arg* is absent, all trap(s) *n* are reset to their original values. If *arg* is the null string, this signal is ignored by the shell and by the commands it invokes. If *n* is 0, the command *arg* is executed on exit from the shell. The **trap** command with no arguments prints a list of commands associated with each signal number.

type [*name* ...]

For each *name*, indicate how it would be interpreted if used as a command name.

ulimit [[**-f**] *n*]

imposes a size limit of *n* blocks on files.

-f imposes a size limit of *n* blocks on files written by child processes (files of any size may be read). Any user may decrease the file size limit, but only the super-user (root) can increase the limit. With no argument, the current limit is printed.

If no option is given and a number is specified, **-f** is assumed.

unset [*name* ...]

For each *name*, remove the corresponding variable or function. The variables **PATH**, **PS1**, **PS2**, **MAILCHECK** and **IFS** cannot be unset.

umask [*ooo*]

The user file-creation mask is set to the octal number *ooo* where *o* is an octal digit (see *umask*(C)). If *ooo* is omitted, the current value of the mask is printed.

wait [*n*]

Waits for the specified process to terminate, and reports the termination status. If *n* is not given, all currently active child processes are waited for. The return code from this command is always 0.

Invocation

If the shell is invoked through *exec*(S) and the first character of argument 0 is **-**, commands are initially read from **/etc/profile** and then from **\$HOME/.profile**, if such files exist. Thereafter, commands are read as described below, which is also the case when the shell is invoked as **/bin/sh**. The flags below are interpreted by the shell on invocation only; note that unless the **-c** or **-s** flag is specified, the first argument is assumed to be the name of a file containing commands, and the remaining arguments are passed as positional parameters to that command file:

- c** *string* If the **-c** flag is present, commands are read from *string*.
- s** If the **-s** flag is present or if no arguments remain, commands are read from the standard input. Any remaining arguments specify the positional parameters. Shell output is written to file descriptor 2.
- t** If the **-t** flag is present, a single command is read and executed, and the shell exits. This flag is intended for use by C programs only and is not useful interactively.
- i** If the **-i** flag is present or if the shell input and output are attached to a terminal, this shell is *interactive*. In this case, **TERMINATE** is ignored (so that **kill 0** does not kill an interactive shell) and **INTERRUPT** is caught and ignored (so that **wait** is interruptible). In all cases, **QUIT** is ignored by the shell.
- r** If the **-r** flag is present, the shell is a restricted shell (see *rsh*(C)).

The remaining flags and arguments are described under the **set** command above.

Exit Status

Errors detected by the shell, such as syntax errors, cause the shell to return a nonzero exit status. If the shell is being used noninteractively, execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed. See the **exit** command above.

Files

/etc/profile
\$HOME/.profile
/tmp/sh*
/dev/null

See Also

cd(C), env(C), login(M), newgrp(C), rsh(C), test(C), umask(C),
dup(S), exec(S), fork(S), pipe(S), signal(S), umask(S), wait(S),
a.out(F), profile(M), environ(M)

Notes

The command **readonly** (without arguments) produces the same output as the command **export**.

If << is used to provide standard input to an asynchronous process invoked by **&**, the shell gets mixed up about naming the input document; a garbage file **/tmp/sh*** is created and the shell complains about not being able to find that file by another name.

If a command is executed, and a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell will continue to **exec** the original command. Use the **hash** command to correct this situation.

If you move the current directory or one above it, **pwd** may not give the correct response. Use the **cd** command with a full path name to correct this situation.

Name

shutdown – Terminates all processing.

Syntax

`/etc/shutdown [time] [su]`

Description

shutdown is part of the XENIX operation procedures. Its primary function is to terminate all currently running processes in an orderly and cautious manner. The *time* argument is the number of minutes before a shutdown will occur. The optional *su* argument lets the user go single-user, without completely shutting down the system. However, the system is shut down for multi-user use. *shutdown* goes through the following steps. First, all users logged on the system are notified to log off the system by a broadcasted message. All file system super-blocks are updated before the system is stopped (see *sync(C)*). This must be done before rebooting the system, to insure file system integrity.

See Also

sync(C), *umount(C)*, *wall(C)*

Diagnostics

The most common error diagnostic that will occur is *device busy*. This diagnostic appears when a particular file system could not be unmounted. See *umount(C)*.

Notes

Once *shutdown* has been invoked, it must be allowed to run to completion and must *not* be interrupted by pressing BREAK or DEL.

shutdown does not lock the hard disk heads.

Name

sleep – Suspends execution for an interval.

Syntax

sleep time

Description

sleep suspends execution for *time* seconds. It is used to execute a command after a certain amount of time as in:

```
(sleep 105; command)&
```

or to execute a command every so often, as in:

```
while true
do
    command
    sleep 37
done
```

See Also

alarm(S), sleep(S)

Notes

It is recommended that *time* be less than 65536 seconds.

Name

sort – Sorts and merges files.

Syntax

```
sort [-cmu] [-ooutput] [-ykmem] [-zrecsz] [-dflMnr] [-btx] [+pos1]
[-pos2] [files]
```

Description

sort sorts lines of all the named files together and writes the result on the standard output. The standard input is read if - is used as a file name or if no input files are named.

Comparisons are based on one or more sort keys extracted from each line of input. By default, there is one sort key, the entire input line, and ordering is lexicographic by bytes in the machine's collating sequence.

The following options alter the default behavior:

- c Check that the input file is sorted according to the ordering rules; give no output unless the file is out of sort.
- m Merge only, the input files are already sorted.
- u Unique: suppress all but one in each set of lines having equal keys.

-ooutput

The argument given is the name of an output file to use instead of the standard output. This file may be the same as one of the inputs. There may be optional blanks between -o and *output*.

-ykmem

The amount of main memory used by the sort has a large impact on its performance. Sorting a small file in a large amount of memory is a waste. If this option is omitted, *sort* begins using a system default memory size, and continues to use more space as needed. If this option is presented with a value, *kmem*, *sort* will start using that number of kilobytes of memory, unless the administrative minimum or maximum is violated, in which case the corresponding extremum will be used. Thus, -y0 is guaranteed to start with minimum memory. By convention, -y (with no argument) starts with maximum memory.

-zrecsz

The size of the longest line read is recorded in the sort phase so buffers can be allocated during the merge phase. If the sort phase is omitted via the **-c** or **-m** options, a popular system default size will be used. Lines longer than the buffer size will cause *sort* to terminate abnormally. Supplying the actual number of bytes in the longest line to be merged (or some larger value) will prevent abnormal termination.

The following options override the default ordering rules.

- d** "Dictionary" order: only letters, digits and blanks (spaces and tabs) are significant in comparisons.
- f** Fold lower case letters into upper case.
- i** Ignore characters outside the ASCII range 040-0176 in non-numeric comparisons.
- M** Compare as months. The first three non-blank characters of the field are folded to upper case and compared so that "JAN" < "FEB" < ... < "DEC". Invalid fields compare low to "JAN". The **-M** option implies the **-b** option (see below).
- n** An initial numeric string, consisting of optional blanks, an optional minus sign, and zero or more digits with optional decimal point, is sorted by arithmetic value. The **-n** option implies the **-b** option (see below). Note that the **-b** option is only effective when restricted sort key specifications are in effect.
- r** Reverse the sense of comparisons.

When ordering options appear before restricted sort key specifications, the requested ordering rules are applied globally to all sort keys. When attached to a specific sort key (described below), the specified ordering options override all global ordering options for that key.

The notation **+pos1 -pos2** restricts a sort key to one beginning at *pos1* and ending at *pos2*. The characters at positions *pos1* and *pos2* are included in the sort key (provided that *pos2* does not precede *pos1*). A missing **-pos2** means the end of the line.

Specifying *pos1* and *pos2* involves the notion of a field (a minimal sequence of characters followed by a field separator or a newline). By default, the first blank (space or tab) of a sequence of blanks acts as the field separator. All blanks in a sequence of blanks are considered to be part of the next field; for example, all blanks at the beginning of a line are considered to be part of the first field. The treatment of field separators can be altered using the options:

- tx Use *x* as the field separator character; *x* is not considered to be part of a field (although it may be included in a sort key). Each occurrence of *x* is significant (e.g., *xx* delimits an empty field).
- b Ignore leading blanks when determining the starting and ending positions of a restricted sort key. If the **-b** option is specified before the first **+pos1** argument, it will be applied to all **+pos1** arguments. Otherwise, the **b** flag may be attached independently to each **+pos1** or **-pos2** argument (see below).

Pos1 and *pos2* each have the form *m.n* optionally followed by one or more of the flags **b**, **d**, **f**, **i**, **n**, or **r**. A starting position specified by **+m.n** is interpreted to mean the *n*+1st character in the *m*+1st field. A missing *.n* means *.0*, indicating the first character of the *m*+1st field. If the **b** flag is in effect, *n* is counted from the first non-blank in the *m*+1st field; **+m.0b** refers to the first non-blank character in the *m*+1st field.

A last position specified by **-m.n** is interpreted to mean the *n*th character (including separators) after the last character of the *m*th field. A missing *.n* means *.0*, indicating the last character of the *m*th field. If the **b** flag is in effect, *n* is counted from the last leading blank in the *m*+1st field; **-m.1b** refers to the first non-blank in the *m*+1st field.

When there are multiple sort keys, later keys are compared only after all earlier keys compare equal. Lines that otherwise compare equal are ordered with all bytes significant.

Examples

Sort the contents of *infile* with the second field as the sort key:

```
sort +1 -2 infile
```

Sort, in reverse order, the contents of *infile1* and *infile2*, placing the output in *outfile* and using the first character of the second field as the sort key:

```
sort -r -o outfile +1.0 -1.2 infile1 infile2
```

Sort, in reverse order, the contents of *infile1* and *infile2* using the first non-blank character of the second field as the sort key:

```
sort -r +1.0b -1.1b infile1 infile2
```

Print the password file (*passwd*(M)) sorted by the numeric user ID (the third colon-separated field):

```
sort -t: +2n -3 /etc/passwd
```

Print the lines of the already sorted file *infile*, suppressing all but the first occurrence of lines having the same third field (the options **-um** with just one input file make the choice of a unique representative from a set of equal lines predictable):

```
sort -um +2 -3 infile
```

Files

/usr/tmp/stm???

See Also

comm(C), join(C), uniq(C)

Diagnostics

Comments and exits with non-zero status for various trouble conditions (e.g., when input lines are too long), and for disorders discovered under the **-c** option. When the last line of an input file is missing a **newline** character, *sort* appends one, prints a warning message, and continues.

Name

`split` – Splits a file into pieces.

Syntax

`split [-n] [file [name]]`

Description

split reads *file* and writes it in as many *n*-line pieces as necessary (default 1000), onto a set of output files. The name of the first output file is *name* with *aa* appended, and so on lexicographically. If no output name is given, *x* is default.

If no input file is given, or if a dash (*-*) is given instead, the standard input file is used.

See Also

`bfs(C)`, `csplit(C)`

Name

stty – Sets the options for a terminal.

Syntax

stty [**-a**] [**-g**] [options]

Description

stty sets certain terminal I/O options for the device that is the current standard input. Without arguments, it reports the settings of certain options; with the **-a** option, it reports all of the option settings; with the **-g** option, it reports current settings in a form that can be used as an argument to another *stty* command. Detailed information about the modes listed in the first five groups below may be found in *termio*(M). Options in the last group are implemented using options in the previous groups. The options are selected from the following:

*Control Modes***parenb (-parenb)**

Enables (disables) parity generation and detection.

parodd (-parodd)

Selects odd (even) parity.

cs5 cs6 cs7 cs8

Selects character size (see *termio*(M)).

0 Hangs up phone line immediately.

50 75 110 134 150 200 300 600

1200 1800 2400 4800 9600 exta

Sets terminal baud rate to the number given, if possible.

hupcl (-hupcl)

Hangs up (does not hang up) phone connection on last close.

hup (-hup)

Same as **hupcl (-hupcl)**.

cstopb (-cstopb)

Uses two(one) stop bits per character.

cread (-cread)

Enables (disables) the receiver.

clocal (-clocal)

Assumes a line without (with) modem control.

*Input Modes***ignbrk (-ignbrk)**

Ignores (does not ignore) break on input.

brkint (-brkint)

Signals (does not signal) INTR on break.

ignpar (-ignpar)

Ignores (does not ignore) parity errors.

parmrk (-parmrk)

Marks (does not mark) parity errors (see *termio*(M)).

inpck (-inpck)

Enables (disables) input parity checking.

istrip (-istrip)

Strips (does not strip) input characters to 7 bits.

inlcr (-inlcr)

Maps (does not map) NL to CR on input.

igncr (-igncr)

Ignores (does not ignore) CR on input.

icrnl (-icrnl)

Maps (does not map) CR to NL on input.

iuclic (-iuclic)

Maps (does not map) uppercase alphabets to lowercase on input.

ixon (-ixon)

Enables (disables) START/STOP output control. Output is stopped by sending an ASCII DC3 and started by sending an ASCII DC1.

ixany (-ixany)

Allows any character (only DC1) to restart output.

ixoff (-ixoff)

Requests that the system send (not send) START/STOP characters when the input queue is nearly empty/full.

*Output Modes***opost (-opost)**

Post-processes output (does not post-process output; ignores all other output modes).

olcuc (-olcuc)

Maps (does not map) lowercase alphabets to uppercase on output.

onlcr (-onlcr)

Maps (does not map) NL to CR-NL on output.

ocrnl (-ocrnl)

Maps (does not map) CR to NL on output.

onocr (-onocr)

Does not (does) output CRs at column zero.

onlret (-onlret)

On the terminal NL performs (does not perform) the CR function.

ofill (-ofill)

Uses fill characters (use timing) for delays.

ofdel (-ofdel)

Fill characters are DELs (NULs).

cr0 cr1 cr2 cr3

Selects style of delay for carriage returns (see *termio*(M)).

nl0 nl1

Selects style of delay for linefeeds (see *termio*(M)).

tab0 tab1 tab2 tab3

Selects style of delay for horizontal tabs (see *termio*(M)).

bs0 bs1

Selects style of delay for backspaces (see *termio*(M)).

ff0 ff1

Selects style of delay for form feeds (see *termio*(M)).

vt0 vt1

Selects style of delay for vertical tabs (see *termio*(M)).

*Local Modes***isig (-isig)**

Enables (disables) the checking of characters against the special control characters INTR and QUIT.

icanon (-icanon)

Enables (disables) canonical input (ERASE and KILL processing).

xcase (-xcase)

Canonical (unprocessed) upper/lowercase presentation.

echo (-echo)

Echoes back (does not echo back) every character entered.

echoe (-echoe)

Echoes (does not echo) ERASE character as a backspace-space-backspace string. Note: this mode will erase the ERASEd character on many CRT terminals; however, it does *not* keep track of column position and, as a result, may be confusing on escaped characters, tabs, and backspaces.

echok (-echok)

Echoes (does not echo) NL after KILL character.

lfkc (-lfkc)

The same as **echok (-echok)**; obsolete.

echonl (-echonl)

Echoes (does not echo) NL.

noflsh (-noflsh)

Disables (enables) flush after INTR or QUIT.

*Control Assignments**control-character C*

Sets *control-character* to *C*, where *control-character* is **erase**, **kill**, **intr**, **quit**, **eof**, **eol**. If *C* is preceded by a caret (^) (escaped from the shell), the value used is the corresponding Ctrl character (e.g., "^D" is a Ctrl-d); "^?" is interpreted as DEL and "^-" is interpreted as undefined.

min i, time i (0 < i < 127)

When **-icanon** is not set, read requests are not satisfied until at least **min** characters have been received or the timeout value **time** has expired. See *tty(C)*.

line *i*

Sets the line discipline to *i* ($0 < i < 127$). There are currently no line disciplines implemented.

*Combination Modes***evenp or parity**

Enables **parenb** and **cs7**.

oddp

Enables **parenb**, **cs7**, and **parodd**.

-parity, -evenp, or -oddp

Disables **parenb**, and sets **cs8**.

raw (-raw or cooked)

Enables (disables) raw input and output (no ERASE, KILL, INTR, QUIT, EOT, or output post processing).

nl (-nl)

Unsets (sets) **icrnl**, **onlcr**. In addition **-nl** unsets **inlcr**, **igncr**, **ocrnl**, and **onlret**.

lcase (-lcase)

Sets (unsets) **xcase**, **iucLC**, and **olcuc**.

LCASE (-LCASE)

Same as **lcase (-lcase)**.

tabs (-tabs or tab3)

Preserves (expands to spaces) tabs when printing.

ek Resets ERASE and KILL characters back to normal Ctrl-H and Ctrl-U .**sane**

Resets all modes to some reasonable values. Useful when a terminal's settings have been hopelessly scrambled.

term

Sets all modes suitable for the terminal type *term*, where *term* is one of **tty33**, **tty37**, **vt05**, **tn300**, **ti700**, or **tek**.

ioctl(S), **tty(M)**, **termio(M)**

STTY (C)

STTY (C)

Notes

Many combinations of options make no sense, but no checking is performed.

Name

`su` – Makes the user a super-user or another user.

Syntax

```
su [ - ] [ name [ arg ... ] ]
```

Description

`su` allows you to become another user without logging off. The default user *name* is *root* (i.e., super-user).

To use `su`, the appropriate password must be supplied (unless you are already a super-user). If the password is correct, `su` will execute a new shell with the real and effective user ID set to that of the specified user. The new shell will be the optional program named in the shell field of the specified user's password file (`/bin/sh` if none is specified (see `sh(C)`). To restore normal user ID privileges, press EOF (Ctrl-D) to the new shell.

Any additional arguments given on the command line are passed to the program invoked as the shell. When using programs like `sh(C)`, an *arg* of the form `-c string` executes *string* via the shell and an *arg* of `-r` gives the user a restricted shell.

The following statements are true only if the optional program named in the shell field of the specified user's password file entry is like `sh(C)`. If the first argument to `su` is a `-`, the environment is changed to what would be expected if the user actually logged in as the specified user. This is done by invoking the program used as the shell with an *arg0* value whose first character is `-`, thus causing first the system's profile (`/etc/profile`) and then the specified user's profile (`.profile` in the new HOME directory) to be executed. Otherwise, the environment is passed along with the possible exception of `$PATH`, which is set to `/bin:/etc:/usr/bin` for *root*. Note that if the optional program used as the shell is `/bin/sh`, the user's `.profile` can check *arg0* for `-sh` or `-su` to determine if it was invoked by `login(M)` or `su(C)`, respectively. If the user's program is other than `/bin/sh`, then `.profile` is invoked with an *arg0* of `-program` by both `login(M)` and `su(C)`.

If you want to log all attempts by users to become root, create the file `/etc/default/su`. In this file, place a string similar to: `SULOG=/usr/adm/sulog`. This causes all attempts by any user to switch user id's to be recorded in the file `/usr/adm/sulog`. This can be any arbitrary filename. The `su` logfile records the original user, the UID of the `su` attempt, and the time of the attempt. If the attempt is successful, a plus sign (+) is placed on the line describing the attempt. A minus sign (-) indicates an unsuccessful attempt.

Examples

To become user **bin** while retaining your previously exported environment, enter:

```
su bin
```

To become user **bin** but change the environment to what would be expected if **bin** had originally logged in, enter:

```
su - bin
```

To execute *command* with the temporary environment and permissions of user **bin**, enter:

```
su - bin -c "command args"
```

Files

<code>/etc/passwd</code>	The system password file
<code>/etc/default/su</code>	Optional file giving location of <code>sulog</code> .
<code>/etc/profile</code>	The system profile
<code>\$HOME/.profile</code>	The user profile

See Also

`env(C)`, `environ(M)`, `login(M)`, `passwd(M)`, `profile(M)`, `sh(C)`

Name

`sum` - Calculates checksum and counts blocks in a file.

Syntax

`sum [-r] file`

Description

sum calculates and prints a 16-bit checksum for the named file, and also prints the number of BSIZE blocks in the file. It is typically used to look for bad spots, or to validate a file communicated over a transmission line. The option `-r` causes an alternate algorithm to be used in computing the checksum.

See Also

`cmchk(C)`, `machine(M)`, `wc(C)`

Diagnostics

“Read error” is indistinguishable from end-of-file on most devices; check the block count.

Notes

Refer to *machine(M)* or use the *cmchk (C)* utility to determine BSIZE for your system.

Name

sync – Updates the super-block.

Syntax

sync

Description

sync executes the *sync* system primitive. If the system is to be stopped, *sync* must be called to ensure file system integrity. Note that *shutdown*(C) automatically calls *sync* before shutting down the system.

See Also

sync(S)

Name

`sysadmin` – Performs file system backups and restores files.

Syntax

`/etc/sysadmin`

Description

sysadmin is a script for performing file system backups and for restoring files from backup disks. It can do a daily incremental backup (level 9), or a periodic full backup (level 0). It can provide a listing of the files backed up and also has a facility to restore individual files from a backup.

sysadmin operates on XENIX format diskettes. The version provided backs up the root file system. The script can be edited to operate on additional file systems if required.

You must be the super-user to use this program.

Files

`/tmp/backup.list`

See Also

`backup(C)`, `restore(C)`, `mkfs(C)`, `dumpdir(C)`

Notes

To add an extra drive, edit the *sysadmin* shell script.

Name

`tail` – Delivers the last part of a file.

Syntax

`tail [±[number][lbc] [-f]] [file]`

Description

tail copies the named file to the standard output beginning at a designated place. If no file is named, the standard input is used.

Copying begins at distance *+number* from the beginning, or *-number* from the end of the input (if *number* is null, the value 10 is assumed). *Number* is counted in units of lines, blocks, or characters, according to the appended option *l*, *b*, or *c*. When no units are specified, counting is by lines.

With the *-f* (“follow”) option, if the input file is not a pipe, the program will not terminate after the line of the input file has been copied, but will enter an endless loop, wherein it sleeps for a second and then attempts to read and copy further records from the input file. Thus it may be used to monitor the growth of a file that is being written by some other process. For example, the command:

`tail -f file`

will print the last ten lines of *file*, followed by any lines that are appended to *file* between the time *tail* is initiated and killed.

See Also

`dd(C)`

Notes

Tails relative to the end of the file are kept in a buffer, and thus are limited in length. Unpredictable results can occur if character special files are “tailed”.

Name

tar – Archives files.

Syntax

tar [key] [files]

Description

tar saves and restores files to and from an archive medium, which is typically a storage device such as floppy disk or tape, or a regular file. Its actions are controlled by the *key* argument. The *key* is a string of characters containing at most one function letter and possibly one or more function modifiers. Valid function letters are **c**, **t**, **x**, and **e**. Other arguments to the command are *files* (or directory names) specifying which files are to be backed up or restored. In all cases, appearance of a directory name refers to the files and (recursively) subdirectories of that directory. The **r** and **u** option cannot be used with tape devices.

The function portion of the key is specified by one of the following letters:

- r** The named *files* are written to the end of the archive. The **c** function implies this function.
- x** The named *files* are extracted from the archive. If a named file matches a directory whose contents had been written onto the archive, this directory is (recursively) extracted. The owner, modification time, and mode are restored (if possible). If no *files* argument is given, the entire contents of the archive are extracted. Note that if several files with the same name are on the archive, the last one overwrites all earlier ones.
- t** The names of the specified files are listed each time that they occur on the archive. If no *files* argument is given, all the names on the archive are listed.
- u** The named *files* are added to the archive if they are not already there, or if they have been modified since last written on that archive.
- c** Creates a new archive; writing begins at the beginning of the archive, instead of after the last file. This command implies the **r** function.

The following characters may be used in addition to the letter that selects the desired function:

- 0,...,7** This modifier selects the drive on which the archive is mounted. The default is found in the file `/etc/default/tar`.
- v** Normally, *tar* does its work silently. The **v** (verbose) option causes it to display the name of each file it treats, preceded by the function letter. With the **t** function, **v** gives more information about the archive entries than just the name.
- w** Causes *tar* to display the action to be taken, followed by the name of the file, and then wait for the user's confirmation. If a word beginning with **y** is given, the action is performed. Any other input means "no".
- f** Causes *tar* to use the next argument as the name of the archive instead of the default device listed in `/etc/default/tar`. If the name of the file is a dash (**-**), *tar* writes to the standard output or reads from the standard input, whichever is appropriate. Thus, *tar* can be used as the head or tail of a pipeline. *tar* can also be used to move hierarchies with the command:

```
cd fromdir; tar cf - . | (cd todir; tar xf -)
```
- b** Causes *tar* to use the next argument as the blocking factor for archive records. The default is 1, the maximum is 20. This option should only be used with raw magnetic tape archives (see **f** above). The block size is determined automatically when reading tapes (key letters **x** and **t**).
- F** Causes *tar* to use the next argument as the name of a file from which succeeding arguments are taken.
- l** Tells *tar* to display an error message if it cannot resolve all of the links to the files being backed up. If **l** is not specified, no error messages are displayed.
- m** Tells *tar* to not restore the modification times. The modification time of the file is the time of extraction.
- k** Causes *tar* to use the next argument as the size of an archive volume in kilobytes. The minimum value allowed is 250. This option is useful when the archive is not intended for a magnetic tape device, but for some fixed size device, such as floppy disk (See **f** above). Very large files are split into "extents" across volumes. When restoring from a multivolume archive, *tar* only prompts for a new volume if a split file has been partially restored.

To override the value of **k** in the **default** file, specify **k** as 0 on the command line.

- e** Prevents files from being split across volumes (tapes or floppy disks). If there is not enough room on the present volume for a given file, *tar* prompts for a new volume. This is only valid when the **k** option is also specified on the command line.
- n** Indicates the archive device is not a magnetic tape. The **k** option implies this. Listing and extracting the contents of an archive are sped because *tar* can seek over files it wishes to skip. Sizes are printed in kilobytes instead of tape blocks.
- p** Indicates that files are extracted using their original permissions. It is possible that a non-super-user may be unable to extract files because of the permissions associated with the files or directories being extracted.
- A** Suppresses absolute filenames. Any leading "/" characters are removed from filenames. During extraction arguments given should match the relative (rather than the absolute) pathnames. With the **c**, **r**, **u** options the **A** options can be used to inhibit putting leading slashes in the archive headers.

tar reads **/etc/default/tar** to obtain default values for the device, blocking factor, volume size, and the device type (tape or non-tape). If no numeric key is specified on the command, *tar* looks for a line in the **default** file beginning with the string **archive0=**. Following this pattern are 4 blank separated strings indicating the values for the device, blocking factor, volume size and device type, in that order. A volume size of '0' indicates infinite volume length, (the previous default value of volume) and is suitable for magnetic tape media. An example **/etc/default/tar** line follows:

```
archive0=/dev/fd0 1 400 n
```

The **n** in the last field, means that this device is not a tape. Use **y** for tape devices. Any default value may be overridden on the command line. The numeric keys (0-7) select the line from the default value beginning with **archive#**=, where **#** is the numeric key. When the **f** key letter is specified on the command line, the entry **"archivef="** is used. In this case, the default file entry must still contain 4 strings, but the first entry (specifying the device) is not significant. The default file **/etc/default/tar** need not exist if a device is specified on the command line.

Examples

If the name of a floppy disk device is `/dev/fd1`, then a tar format file can be created on this device by entering:

```
assign /dev/fd
tar cvfk /dev/fd1 360 files
```

where *files* are the names of files you want archived and 360 is the capacity of the floppy disk in kilobytes. Note that arguments to key letters are given in the same order as the key letters themselves, thus the `fk` key letters have corresponding arguments `/dev/fd1` and `360`. Note that if a *file* is a directory, the contents of the directory are recursively archived. To display a listing of the archive, enter:

```
tar tvf /dev/fd1
```

At some later time you will likely want to extract the files from the archive floppy. You can do this by entering:

```
tar xvf /dev/fd1
```

The above command extracts all files from the archive, using the exact same pathnames as used when the archive was created. Because of this behavior, it is normally best to save archive files with relative pathnames rather than absolute ones, since directory permissions may not let you read the files into the absolute directories specified. (See the `A` flag under *Options*.)

In the above examples, the `v` verbose option is used simply to confirm the reading or writing of archive files on the screen. Also, a normal file could be substituted for the floppy device `/dev/fd1` shown in the examples.

Files

<code>/etc/default/tar</code>	Default devices, blocking and
<code>/tmp/tar*</code>	volume sizes, device type

Diagnostics

Displays an error message about bad key characters and archive read/write errors.

Displays an error message if not enough memory is available to hold the link tables.

Notes

There is no way to ask for the *n*th occurrence of a file.

The **u** option can be slow.

The limit on filename length is 100 characters.

When archiving a directory that contains subdirectories, *tar* will only access those subdirectories that are within 17 levels of nesting. Subdirectories at higher levels will be ignored after *tar* displays an error message.

Systems with a 1K-byte file system cannot specify raw disk devices unless the **b** option is used to specify an even number of blocks. This means that one cannot update a raw-mode disk partition.

Do not enter:

```
tar xff --
```

This would imply taking two things from the standard input at the same time.

Use error-free floppy disks for best results with *tar*.

Name

tee – Creates a tee in a pipe.

Syntax

```
tee [ -i ] [ -a ] [ -u ] [ file ] ...
```

Description

tee transcribes the standard input to the standard output and makes copies in the *files*. The **-i** option ignores interrupts; the **-a** option causes the output to be appended to the *files* rather than overwriting them. The **-u** option causes the output to be unbuffered.

Examples

The following example illustrates the creation of temporary files at each stage in a pipeline:

```
grep ABC | tee ABC.grep | sort | tee ABC.sort | more
```

This example shows how to tee output to the terminal screen:

```
grep ABC | tee /dev/ttyxx | sort | uniq >final.file
```

Name

test – Tests conditions.

Syntax

test *expr*

[*expr*]

Description

test evaluates the expression *expr* , and if its value is true, returns a zero (true) exit status; otherwise, *test* returns a nonzero exit status if there are no arguments. The following primitives are used to construct *expr*:

- r *file*** True if *file* exists and is readable.
- w *file*** True if *file* exists and is writable.
- x *file*** True if *file* exists and is executable.
- f *file*** True if *file* exists and is a regular file.
- d *file*** True if *file* exists and is a directory.
- c *file*** True if *file* exists and is a character special file.
- b *file*** True if *file* exists and is a block special file.
- u *file*** True if *file* exists and its set-user-ID bit is set.
- g *file*** True if *file* exists and its set-group-ID bit is set.
- k *file*** True if *file* exists and its sticky bit is set.
- s *file*** True if *file* exists and has a size greater than zero.
- t [*fildev*]** True if the open file whose file descriptor number is *fildev* (1 by default) is associated with a terminal device.
- z *s1*** True if the length of string *s1* is zero.
- n *s1*** True if the length of the string *s1* is nonzero.
- s1* = *s2*** True if strings *s1* and *s2* are identical.

- s1* != *s2* True if strings *s1* and *s2* are *not* identical.
- s1* True if *s1* is *not* the null string.
- n1* -eq *n2* True if the integers *n1* and *n2* are algebraically equal.
Any of the comparisons **-ne**, **-gt**, **-ge**, **-lt**, and **-le**
may be used in place of **-eq**.

These primaries may be combined with the following operators:

- !** Unary negation operator
- a** Binary *and* operator
- o** Binary *or* operator (**-a** has higher precedence than **-o**)
- (*expr*) Parentheses for grouping

Notice that all the operators and flags are separate arguments to *test*. Notice also, that parentheses are meaningful to the shell and, therefore, must be escaped.

See Also

find(C), sh(C)

Warning

In the second form of the command (i.e., the one that uses **[]**, rather than the word *test*), the square brackets must be delimited by blanks.

Name

`touch` - Updates access and modification times of a file.

Syntax

`touch [-amc] [mmddhhmm[yy]] files`

Description

touch causes the access and modification times of each argument to be updated. If no time is specified (see *date(C)*) the current time is used. The first *mm* refers to the month, *dd* refers to the day, *hh* refers to the hour, the second *mm* refers to the minute, and *yy* refers to the year. The *-a* and *-m* options cause *touch* to update only the access or modification times respectively (default is *-am*). The *-c* option silently prevents *touch* from creating the file if it did not previously exist.

The return code from *touch* is the number of files for which the times could not be successfully modified (including files that did not exist and were not created).

See Also

`date(C)`, `utime(S)`

Name

tr – Translates characters.

Syntax

tr [-cds] [string1 [string2]]

Description

tr copies the standard input to the standard output with substitution or deletion of selected characters. Input characters found in *string1* are mapped into the corresponding characters of *string2*. Any combination of the options -cds may be used:

- c Complements the set of characters in *string1* with respect to the universe of characters whose ASCII codes are 001 through 377 octal
- d Deletes all input characters in *string1*
- s Squeezes all strings of repeated output characters that are in *string2* to single characters

The following abbreviation conventions may be used to introduce ranges of characters or repeated characters into the strings:

- [a-z] Stands for the string of characters whose ASCII codes run from character *a* to character *z*, inclusive.
- [a*n] Stands for *n* repetitions of *a*. If the first digit of *n* is 0, *n* is considered octal; otherwise, *n* is taken to be decimal. A zero or missing *n* is taken to be huge; this facility is useful for padding *string2*.

The escape character \ may be used as in the shell to remove special meaning from any character in a string. In addition, \ followed by 1, 2, or 3 octal digits, stands for the character whose ASCII code is given by those digits.

The following example creates a list of all the words in *file1*, one per line in *file2*, where a word is taken to be a maximal string of alphabets. The strings are quoted to protect the special characters from interpretation by the shell; 012 is the ASCII code for new-line:

```
tr -cs "[A-Z][a-z]" "[\012*]" <file1 >file2
```

See Also

ed(C), sh(C), ascii(M)

Notes

Won't handle ASCII NUL in *string1* or *string2*; always deletes NUL from input.

Name

true – Returns with a zero exit value.

Syntax

true

Description

true does nothing except return with a zero exit value. *false*(C), *true*'s counterpart, does nothing except return with a nonzero exit value. *true* is typically used in shell procedures such as:

```
while true
do
    command
done
```

See Also

sh(C), false (C)

Diagnostics

true has exit status zero.

Name

`tset` – Sets terminal modes.

Syntax

```
tset [ - ] [ -hrsuiQS ] [ -e[c] ] [ -E[c] ] [ -k[c] ]
[ -m [ident][test baudrate]:type ] [ type ]
```

Description

`tset` causes terminal dependent processing such as setting erase and kill characters, setting or resetting delays, and the like. It is driven by the `/etc/ttytype` and `/etc/termcap` files.

The type of terminal is specified by the *type* argument. The type may be any type given in `/etc/termcap`. If *type* is not specified, the terminal type is the value of the environment variable `TERM`, unless the `-h` flag is set or any `-m` argument is given. In this case, the type is read from `/etc/ttytype` (the port name to terminal type database). The port name is determined by a `ttyname(S)` call on the diagnostic output. If the port is not found in `/etc/ttytype` the terminal type is set to *unknown*.

Ports for which the terminal type is indeterminate are identified in `/etc/ttytype` as *dialup*, *plugboard*, etc. The user can specify how these identifiers should map to an actual terminal type. The mapping flag, `-m`, is followed by the appropriate identifier (a four-character or longer substring is adequate), an optional test for baud rate, and the terminal type to be used if the mapping conditions are satisfied. If more than one mapping is specified, the first correct mapping prevails. A missing identifier matches all identifiers. Baud rates are specified as with `stty(C)`, and are compared with the speed of the diagnostic output. The test may be any combination of: `>`, `=`, `<`, `@`, and `!`. (Note: `@` is a synonym for `=` and `!` inverts the sense of the test. Remember that escape characters are meaningful to the shell.)

If the *type* as determined above begins with a question mark, the user is asked if he really wants that type. A null response means to use that type; otherwise, another type can be entered which will be used instead. (The question mark must be escaped to prevent filename expansion by the shell.)

`tset` is most useful when included in the `.login` (for `csh(C)`) or `.profile` (for `sh(C)`) file executed automatically at login, with `-m` mapping used to specify the terminal type you most frequently dial in on.

Options

- e** This option sets the erase character to the named character, *c*, with *c* defaulting to Ctrl-H.
- E** This flag is identical to **-e** except that it only operates on terminals that can backspace.
- k** This option sets the kill character to the named character, *c*, with *c* defaulting to Ctrl-U. In all of these flags, “*X*” where *X* is any character is equivalent to Ctrl-*X*.
- This option prints the terminal type on the standard output; this can be used to get the terminal type by entering:

```
set termtype = `tset -`
```

If no other options are given, *tset* operates in “fast mode” and *only* outputs the terminal type, bypassing all other processing.
- h** Forces *tset* to search */etc/ttytype* for information and to overlook the environment variable, **TERM**.
- s** This option outputs “setenv” commands (if your default shell is *csh*(C) or “export” and assignment commands (if your default shell is *sh*(C));

For the **-s** option with the Bourne shell, enter:

```
tset -s ... > /tmp/tset$$
/tmp/tset$$
rm /tmp/tset$$
```

- S** This option only outputs the strings to be placed in the environment variables.

If you are using *csh*, enter:

```
set noglob
set term=('tset -S ....')
setenv TERM $term[1]
setenv TERMCAP "$term[2]"
unset term
unset noglob
```

- r**
This option displays the terminal type on the diagnostic output.
- Q**
This option suppresses displaying the “Erase set to” and “Kill set to” messages.
- I** This option suppresses outputting the terminal initialization strings.
- m**
This option is the mapping flag. It is used to specify the terminal type you most frequently use. It is followed by the appropriate identifier for your terminal, listed in **/etc/ttytype**. When you log on the system, it sets the terminal type to *ident* unless you specify otherwise.

Examples

```
tset gt42
```

Sets the terminal type to gt42.

```
tset -mdialup\>300:adm3a -mdialup:dw2 -Qr -e#
```

If the entry in **/etc/ttytype** corresponding to the login port is “dialup”, and the port speed is greater than 300 baud, set the terminal type to adm3a. If the **/etc/ttytype** entry is “dialup” and the port speed is less than or equal to 300 baud, set the terminal type to dw2. Set the erase character to “#”, and display the terminal type (but not the erase character) on standard error.

```
tset -m dial:ti733 -m plug:\?hp2621 -m unknown:\? -e -k^U
```

If the **/etc/ttytype** entry begins with “dial”, the terminal type becomes ti733. If the entry begins with “plug”, *tset* prompts with:

```
TERM = (hp2621)
```

Enter the correct terminal type if it is different than that shown. If the entry is “unknown”, *tset* prompts with:

```
TERM = (unknown)
```

In any case erase is set to the terminal’s backspace character, and the terminal type is displayed on standard error and the kill character is set to Ctrl-U.

Files

/etc/ttytype Port name to terminal type map database

/etc/termcap Terminal capability database

See Also

tty(M), termcap(M), stty(C)

Credit

This utility was developed at the University of California at Berkeley and is used with permission.

Name

`tty` – Gets the terminal's name.

Syntax

`tty [-s]`

Description

The `tty` command prints the pathname of the user's terminal on the standard output. The `-s` option inhibits printing, allowing you to test just the exit code.

Exit Codes

0 if the standard input is a terminal, 1 otherwise.

Diagnostics

not a tty If the standard input is not a terminal and `-s` is not specified

Name

umask – Sets file-creation mode mask.

Syntax

umask [*ooo*]

Description

The user file-creation mode mask is set to *ooo*. The three octal digits refer to read/write/execute permissions for *owner*, *group*, and *others*, respectively. Only the low-order 9 bits of *cmask* and the file mode creation mask are used. The value of each specified digit is “subtracted” from the corresponding “digit” specified by the system for the creation of any file (see *umask*(S) or *creat*(S)). This is actually a binary masking operation, and thus the name “umask”. In general, binary ones remove a given permission, and zeros have no effect at all. For example, **umask 022** removes *group* and *others* write permission (files normally created with mode 777 become mode 755 ; files created with mode 666 become mode 644).

If *ooo* is omitted, the current value of the mask is printed.

umask is recognized and executed by the shell. By default, login shells have a umask of 022.

See Also

chmod(C), *sh*(C), *chmod*(S), *creat*(S), *umask*(S)

Name

umount – Dismounts a file structure.

Syntax

/etc/umount special-device

Description

umount announces to the system that the removable file structure previously mounted on device *special-device* is to be removed. Any pending I/O for the file system is completed, and the file structure is flagged clean. For a detailed explanation of the mounting process, see *mount(C)*.

Files

/etc/mnttab Mount table

See Also

mount(C), mount(S), mnttab(F)

Diagnostics

<i>device busy</i>	An executing process is using a file on the named file system
--------------------	---

Name

uname – Prints the name of the current XENIX system.

Syntax

uname [-snrmvdupa]

Description

uname prints the current system name of the XENIX system on the standard output file. It is primarily used to determine which system you are using. The options cause selected information returned by *uname*(S) to be printed:

- s Prints the system name (default).
- n Prints the nodename (the nodename may be a name that the system is known by to a communications network).
- r Prints the operating system release.
- m Manufacturer prints original supplier (number) of XENIX system.
- v Prints the operating system version.
- d Distributor prints OEM (number) for the system.
- u Prints user serial number.
- p Prints processor of the machine.
- a Prints all the above information.

See Also

uname(S)

Name

uniq - Reports repeated lines in a file.

Syntax

uniq [**-udc** [**+n**] [**-n**]] [input [output]]

Description

uniq reads the *input* file and compares adjacent lines. In the normal case, the second and succeeding copies of repeated lines are removed; the remainder is written on the output file. *Input* and *output* should always be different. Note that repeated lines must be adjacent in order to be found; see *sort*(C). If the **-u** flag is used, just the lines that are not repeated in the original file are output. The **-d** option specifies that one copy of just the repeated lines is to be written. The normal mode output is the union of the **-u** and **-d** mode outputs.

The **-c** option supersedes **-u** and **-d** and generates an output report in default style but with each line preceded by a count of the number of times it occurred.

The *n* arguments specify skipping an initial portion of each line in the comparison:

- n** The first *n* fields together with any blanks before each are ignored. A field is defined as a string of nonspace, nontab characters separated by tabs and spaces from its neighbors.
- +n** The first *n* characters are ignored. Fields are skipped before characters.

See Also

comm(C), sort(C)

Name

units – Converts units.

Syntax

units

Description

units converts quantities expressed in various standard scales to their equivalents in other scales. It works interactively in this fashion:

You have: **inch**
 You want: **cm**
 * 2.540000e+00
 / 3.937008e-01

A quantity is specified as a multiplicative combination of units optionally preceded by a numeric multiplier. Powers are indicated by suffixed positive integers, division is shown by the usual sign:

You have: **15 lbs force/in2**
 You want: **atm**
 * 1.020689e+00
 / 9.797299e-01

units only does multiplicative scale changes; thus it can convert Kelvin to Rankine, but not Centigrade to Fahrenheit. Most familiar units, abbreviations, and metric prefixes are recognized, as well as the following:

pi Ratio of circumference to diameter

c Speed of light

e Charge on an electron

g Acceleration of gravity

force Same as **g**

mole
 Avogadro's number

water
 Pressure head per unit height of water

au Astronomical unit

Pound is not recognized as a unit of mass; **lb** is. Compound names are run together, (e.g. **lightyear**). British units that differ from their US counterparts are prefixed with "br". For a complete list of units, enter:

cat /usr/lib/unittab

Files

/usr/lib/unittab

Name

uuclean - Clean-up the uucp spool directory.

Syntax

uuclean [options] ...

Description

uuclean scans the spool directory for files with the specified prefix and deletes all those which are older than the specified number of hours.

The following options are available:

- ddirectory** Clean *directory* instead of the spool directory.
- ppre** Scan for files with *pre* as the file prefix. Up to 10 **-p** arguments may be specified. A **-p** without any *pre* following will cause all files older than the specified time to be deleted.
- ntime** Files whose age is more than *time* hours are deleted if the prefix test is satisfied. (Default time is 72 hours.)
- m** Send mail to the owner of the file when it is deleted.

This program will typically be started by *cron*(C).

Files

/usr/lib/uucp	directory with commands used by <i>uuclean</i> internally
/usr/spool/uucp	spool directory

See Also

uucp(C), uux(C).

Name

uucp, *uulog*, *uname* - Copies files from XENIX to XENIX.

Syntax

uucp [option] ... source-file ... destination-file

uulog [option] ...

uname [-l]

Description

uucp copies files named by the source-file arguments to the destination-file argument. A filename may be a pathname on your machine, or may have the form:

system-name!pathname

where "system-name" is taken from a list of system names which *uucp* knows about. Shell metacharacters *?*[]* appearing in *pathname* will be expanded on the appropriate system.

Pathnames may be a full pathname, or a pathname preceded by *~user* where *user* is a user ID on the specified system and is replaced by that user's login directory. Anything else is prefixed by the current directory.

If the result is an erroneous pathname for the remote system, the copy will fail. If the destination file is a directory, the last part of the source filename is used.

uucp preserves execute permissions across the transmission and gives 0666 read and write permissions (see *chmod(S)*).

The following options are interpreted by *uucp*:

- d Makes all necessary directories for the file copy.
- c Uses the source file when copying out rather than copying the file to the spool directory.
- m Sends mail to you when the copy is complete.

uulog maintains a summary log of *uucp* and *uux(C)* transactions in the file */usr/spool/uucp/LOGFILE* by gathering information from partial log files named */usr/spool/uucp/LOG.*.?*. *uulog* removes the partial log files.

The options cause *uulog* to display log information:

-ssys

Displays information about work involving system *sys*.

-uuser

Displays information about work done for the specified *user*.

uname displays the *uucp* names of known systems. The **-l** option returns the local system name. A description is displayed for each system that has a line of information in */usr/lib/uucp/ADMIN*. The format of *ADMIN* is:

```
sysname tab description tab
```

Files

<i>/usr/spool/uucp</i>	Spool directory
<i>/usr/spool/uucppublic</i>	Public directory for receiving and sending
<i>/usr/lib/uucp/*</i>	Other data and program files

See Also

uux(C), *mail*(C), *uucinstall*(C), *uuto*(C)

Notes

For security reasons, all files received by *uucp* should be owned by *uucp*.

The **-m** option will only work sending files or receiving a single file. Receiving multiple files specified by special shell characters *?*[]* will not activate the **-m** option.

This version of *uucp* is based on a version 7 implementation.

Warning

For security reasons, file access should be, and usually is, severely restricted. You probably will not be able to copy or manipulate arbitrary files, or execute many commands, on a remote machine.

Similarly, you may not be able to send files to arbitrary, remote pathnames. As distributed, the remotely accessible files are in */usr/spool/uucppublic*.

Name

uuinstall – Administer UUCP control files.

Syntax

/etc/uuinstall [-r]

Description

The *uuinstall* program is used to manage the content of the control files used by the *uucp* communications system. It allows the user to change the contents of these files without using a text editor. The user need not know the detailed format of each of the control files, although he must be familiar with the function of the various fields within the files. These details are explained in the *XENIX User's Guide*.

The *uuinstall* program can only be executed by the super-user. When invoked with the optional **-r** flag, *uuinstall* will not allow any of the files to be modified whether or not the user has made changes to the files.

If *uuinstall* finds any of the required **uucp** control files missing from the system, it will create them with the correct access permissions and ownership.

Files

/etc/systemid
/usr/lib/uucp/USERFILE
/usr/lib/uucp/L.sys
/usr/lib/uucp/L-devices
/usr/lib/uucp/L-dialcodes

See Also

mkuser(C),
XENIX User's Guide

Name

`uustat` – `uucp` status inquiry and job control.

Syntax

`uustat [-c] [-j] [-k] [-m] [-osuvy] . . .`

Description

`uustat` will display the status of, or cancel, previously specified `uucp` commands, or provide general status on `uucp` connections to other systems. The following options are recognized:

- chour** Remove the status entries which are older than *hour* hours. This administrative option can only be initiated by the user `uucp` or the super-user.
- jall** Report the status of all the `uucp` requests.
- kjobn** Kill the `uucp` request whose job number is *jobn*. The killed `uucp` request must belong to the person issuing the `uustat` command unless he is the super-user.
- mmch** Report the status of accessibility of machine *mch*. If *mch* is specified as `all`, the status of all machines known to the local `uucp` are provided.
- ohour** Report the status of all `uucp` requests which are older than *hour* hours.
- ssys** Report the status of all `uucp` requests which communicate with remote system *sys*.
- uuser** Report the status of all `uucp` requests issued by *user*.
- v** Report the `uucp` status verbosely. If this option is not specified, a status code is displayed with each `uucp` request.
- yhour** Report the status of all `uucp` requests which are younger than *hour* hours.

When no options are given, `uustat` outputs the status of all `uucp` requests issued by the current user. Note that only one of the options `-j`, `-m`, `-k`, or `-c` may be specified at a time.

For example, the command:

```
uustat -uhdc -smhtsa -y72 -v
```

prints the verbose status of all `uucp` requests that were issued by user *hdc* to communicate with system *mhtsa* within the last 72 hours. The job request status format is:

```
job-number user remote-system command-time status-time
```

where the *status* may be either an octal number or a verbose description. The octal code corresponds to the following description:

OCTAL	STATUS
00001	the copy failed, but the reason cannot be determined
00002	permission to access local file is denied
00004	permission to access remote file is denied
00010	bad <i>uucp</i> command is generated
00020	remote system cannot create temporary file
00040	cannot copy to remote directory
00100	cannot copy to local directory
00200	local system cannot create temporary file
00400	cannot execute <i>uucp</i>
01000	copy succeeded
02000	copy finished, job deleted
04000	job is queued

The machine accessibility status format is:

system-name time status

where *time* is the latest status time and *status* is a self-explanatory description of the machine status.

Files

/usr/spool/uucp spool directory
 /usr/lib/uucp/L_stat system status file
 /usr/lib/uucp/R_stat request status file

See Also

uucp(C).

Name

uusub – Monitor uucp network.

Syntax

uusub [options]

Description

uusub defines a *uucp* subnetwork and monitors the connection and traffic among the members of the subnetwork. The following options are available:

- asys** Add *sys* to the subnetwork.
- dsys** Delete *sys* from the subnetwork.
- l** Report the statistics on connections.
- r** Report the statistics on traffic amount.
- f** Flush the connection statistics.
- uhr** Gather the traffic statistics over the past *hr* hours.
- csys** Exercise the connection to the system *sys*. If *sys* is specified as **all**, then exercise the connection to all the systems in the subnetwork.

The connections report format is:

sys #call #ok time #dev #login #nack #other

where *sys* is the remote system name, #*call* is the number of times the local system tries to call *sys* since the last flush was done, #*ok* is the number of successful connections, *time* is the the latest successful connect time, #*dev* is the number of unsuccessful connections because of no available device (e.g. ACU), #*login* is the number of unsuccessful connections because of login failure, #*nack* is the number of unsuccessful connections because of no response (e.g., line busy, system down), and #*other* is the number of unsuccessful connections because of other reasons.

The traffic statistics format is:

sfile *sbyte* *rfile* *rbyte*

where *sfile* is the number of files sent and *sbyte* is the number of bytes sent over the period of time indicated in the latest *uusub* command with the **-uhr** option. Similarly, *rfile* and *rbyte* are the numbers of files and bytes received.

The command:

uusub -c all -u 24

is typically started by *cron*(C) once a day.

Files

/usr/spool/uucp/SYSLOG	
	system log file
/usr/lib/uucp/L_sub	connection statistics
/usr/lib/uucp/R_sub	traffic statistics

See Also

uucp(C), uustat(C).

Name

uuto, uupick – Public XENIX-to-XENIX file copy.

Syntax

uuto [options] source-files destination
uupick [-s system]

Description

uuto sends *source-files* to *destination*. *uuto* uses the *uucp*(CP) facility to send files, while it allows the local system to control the file access. A source-file name is a path name on your machine. Destination has the following format:

system!user

where *system* is taken from a list of system names that *uucp* knows about (see *uuname*(CP)). *Logname* is the login name of someone on the specified system.

Two options are available:

- p** Copy the source file into the spool directory before transmission.
- m** Send mail to the sender when the copy is complete.

The files (or sub-trees if directories are specified) are sent to PUBDIR on *system*, where PUBDIR is a public directory defined in the *uucp* source. Specifically the files are sent to

PUBDIR/receive/user/mysystem/files.

The destined recipient is notified by *mail*(C) of the arrival of files.

Uupick accepts or rejects the files transmitted to the user. Specifically, *uupick* searches PUBDIR for files destined for the user. For each entry (file or directory) found, the following message is printed on the standard output:

from system: [file *file-name*] [dir *dirname*] ?

Uupick then reads a line from the standard input to determine the disposition of the file:

<new-line> Go on to next entry.

d Delete the entry.

m [*dir*] Move the entry to named directory *dir* (current directory is default).

a [*dir*] Same as m except moving all the files sent from *system*.

p Print the content of the file.

q Stop.

EOT (control-d) Same as q.

!command Escape to the shell to do *command*.

***** Print a command summary.

Upick invoked with the *-ssystem* option will only search /usr/spool/uucppublic for files sent from *system*.

Files

/usr/spool/uucppublic public directory

See Also

mail(C), uuclean(C), uucp(C), uuname(C), uustat(C), uux(C).

Name

`uux` - Executes command on remote XENIX.

Syntax

`uux [-] command-string`

Description

`uux` gathers 0 or more files from various systems, executes commands on a specified system, and sends the standard output to a file on a specified system.

The command-string is made up of one or more arguments that look like a shell command line, except that the command and filenames may be prefixed by system-name!. A null system-name is interpreted as the local system.

Filenames may be (1) a full pathname; (2) a pathname preceded by ~xxx; where xxx is a user ID on the specified system and is replaced by that user's login directory; or (3) anything else prefixed by the current directory.

The "-" option causes the standard input to the `uux` command to be the standard input to the command-string.

For example, the command:

```
uux "!diff usg!/usr/dan/f1 pwba!/a4/dan/f1 > !f1.diff"
```

will get the **f1** files from the usg and pwba machines, execute a *diff* command and put the results in **f1.diff** in the local directory.

Any special shell characters such as <>;| should be quoted either by quoting the entire command-string, or quoting the special characters as individual arguments.

Files

/usr/uucp/spool Spool directory

/usr/uucp/* Other data and programs

See Also

`uucp(C)`

Warning

An installation may, and for security reasons generally will, limit the list of commands executable on behalf of an incoming request from *uux*. Typically, a restricted site will permit little other than the receipt of mail via *uux*.

Notes

Only the first command of a shell pipeline may have a system-name!. All other commands are executed on the system of the first command.

The shell metacharacter *** will probably not perform as expected.

The shell tokens *<<* and *>>* are not implemented.

There is no notification of denial of execution on the remote machine.

Name

vi, *view*, *vedit* – Invokes a screen-oriented display editor.

Syntax

vi [*-option...*] [*command*] [*filename*]

view [*-option ...*] [*command ...*] [*filename ...*]

Description

vi offers a powerful set of text editing operations based on a set of mnemonic commands. Most commands are single keystrokes that perform simple editing functions. *vi* displays a full screen “window” into the file you are editing. The contents of this window can be changed quickly and easily within *vi*. While editing, visual feedback is provided (the name *vi* itself is short for “visual”).

The *view* command is the same as *vi* except that the read-only option (**-R**) is set automatically. The file cannot be changed with *view*.

The *vedit* command is the same as *vi* except for differences in the option settings. *vedit* uses **novice** mode, turns off the **magic** option, sets the option **report=1** calls the **showmode** and sets **redraw**.

The **showmode** option informs the *vedit* user, in a message in the lower right hand corner of the screen, which mode is being used. For instance after the **ESC-i** command is used, the message reads “INSERT MODE”.

Note that you can not set the **novice** option from within *vi* or *ex*. If you want to use the **novice** option you must use the *vedit* utility. (It is possible to set the **nonovice** option from within *vedit*.)

vi and the line editor *ex* are one and the same editor: the names *vi* and *ex* identify a particular user interface rather than any underlying functional difference. The differences in user interface, however, are quite striking. *ex* is a powerful line-oriented editor, similar to the editor *ed*. However, in both *ex* and *ed*, visual updating of the terminal screen is limited, and commands are entered on a command line. *vi*, on the other hand, is a screen-oriented editor designed so that what you see on the screen corresponds exactly and immediately to the contents of the file you are editing. In the following discussion, *vi* commands and options are printed in bold-face type.

Options available on the *vi* command line include:

- t Equivalent to an initial *tag* command; edits the file containing the tag and positions the editor at its definition.
- r Used in recovering after an editor or system crash, retrieving the last saved version of the named file. If no file is specified, this option prints a list of saved files.
- l Specific to editing LISP, this option sets the **showmatch** and **lisp** options.
- wn Sets the default window size to *n*. Useful on dialups to start in small windows.
- R Sets a read-only option so that files can be viewed but not edited.

The Editing Buffer

vi performs no editing operations on the file that you name during invocation. Instead, it works on a copy of the file in an "editing buffer."

When you invoke *vi* with a single filename argument, the named file is copied to a temporary editing buffer. The editor remembers the name of the file specified at invocation, so that it can later copy the editing buffer back to the named file. The contents of the named file are not affected until the changes are copied back to the original file.

Modes of Operation

Within *vi* there are three distinct modes of operation:

- | | |
|----------------|--|
| Command Mode | Within command mode, signals from the keyboard are interpreted as editing commands. |
| Insert Mode | Insert mode can be entered by typing any of the <i>vi</i> insert, append, open, substitute, change, or replace commands. Once in insert mode, letters typed at the keyboard are inserted into the editing buffer. |
| ex Escape Mode | The <i>vi</i> and <i>ex</i> editors are one and the same editor differing mainly in their user interface. In <i>vi</i> , commands are usually single keystrokes. In <i>ex</i> , commands are lines of text terminated by a RETURN. <i>vi</i> |

has a special "escape" command that gives access to many of these line-oriented *ex* commands. To use the *ex* escape mode, type a colon (:). The colon is echoed on the status line as a prompt for the *ex* command. An executing command can be aborted by pressing INTERRUPT. Most file manipulation commands are executed in *ex* escape mode (for example, the commands to read in a file and to write out the editing buffer to a file).

Special Keys

There are several special keys in *vi*. The following keys are used to edit, delimit, or abort commands and command lines.

ESC	Used to return to <i>vi</i> command mode or to cancel partially formed commands.
RETURN	Terminates <i>ex</i> commands when in <i>ex</i> escape mode. Also used to start a newline when in insert mode.
INTERRUPT	Often the same as the DEL or RUBOUT key on many terminals. Generates an interrupt, telling the editor to stop what it is doing. Used to abort any command that is executing.
/	Used to specify a string to be searched for. The slash appears on the status line as a prompt for a search string. The question mark (?) works exactly like the slash key, except that it is used to search backward in a file instead of forward.
:	The colon is a prompt for an <i>ex</i> command. You can then type in any <i>ex</i> command, followed by an ESC or RETURN, and the given <i>ex</i> command is executed.

The following characters are special in insert mode:

BKSP	Backs up the cursor one character on the current line. The last character typed before the BKSP is removed from the input buffer, but remains displayed on the screen.
Ctrl-U	Moves the cursor back to the first character of the insertion and restarts insertion.

- Ctrl-V Removes the special significance of the next typed character. Use Ctrl-V to insert control characters. Linefeed and Ctrl-J cannot be inserted in the text except as new-line characters. Ctrl-Q and Ctrl-S are trapped by the operating system before they are interpreted by *vi*, so they too cannot be inserted as text.
- Ctrl-W Moves the cursor back to the first character of the last inserted word.
- Ctrl-T During an insertion, with the **autoindent** option set and at the beginning of the current line, entering this character will insert *shiftwidth* whitespace.
- Ctrl-@ If entered as the first character of an insertion, it is replaced with the last text inserted, and the insertion terminates. Only 128 characters are saved from the last insertion. If more than 128 characters were inserted, then this command inserts no characters. A Ctrl-@ cannot be part of a file, even if quoted.

Starting and Exiting vi

To enter *vi*, enter:

- vi* *Edits empty editing buffer*
- vi file* *Edits named file*
- vi +123 file* *Goes to line 123*
- vi +45 file* *Goes to line 45*
- vi +/word file* *Finds first occurrence of "word"*
- vi +/tty file* *Finds first occurrence of "ty"*

There are several ways to exit the editor:

- ZZ** The editing buffer is written to the file *only* if any changes were made.
- :x** The editing buffer is written to the file *only* if any changes were made.
- :q!** Cancels an editing session. The exclamation mark (!) tells *vi* to quit unconditionally. In this case, the editing buffer is not written out.

vi Commands

vi is a visual editor with a window on the file. What you see on the screen is *vi*'s notion of what the file contains. Commands do not cause any change to the screen until the complete command is entered. Most commands may take a preceding count that specifies repetition of the command. This count parameter is not given in the following command descriptions, but is implied unless overridden by some other prefix argument. When *vi* gets an improperly formatted command, it rings a bell.

Cursor Movement

The cursor movement keys allow you to move your cursor around in a file. Note in particular the direction keys (if available on your terminal), the H, J, K, and L cursor keys, and SPACEBAR, BKSP, Ctrl-N, and Ctrl-P. These three sets of keys perform identical functions.

Forward Space – l, SPACEBAR, or right direction key

Syntax: **l**
 SPACEBAR
 right direction key

Function:

Moves the cursor forward one character. If a count is given, move forward *count* characters. You cannot move past the end of the line.

Backspace – h, BKSP, or left direction key

Syntax: **h**
 BKSP
 left direction key

Function: Moves cursor backward one character. If a count is given, moves backward *count* characters. Note that you cannot move past the beginning of the current line.

Next Line – +, RETURN, j, Ctrl-N, and LF

Syntax: **+**
 RETURN

Function: Moves the cursor down to the beginning of the next line.

Syntax: **j**
 Ctrl-N
 LF
 down direction key

Function: Moves the cursor down one line, remaining in the same column. Note the difference between these commands and the preceding set of next line commands which move to the *beginning* of the next line.

Previous Line – k, Ctrl-P, and up direction key

Syntax: k
Ctrl-P
up direction key

Function: Moves the cursor up one line, remaining in the same column. If a count is given, the cursor is moved *count* lines.

Syntax: –

Function: Moves the cursor up to the beginning of the previous line. If a count is given, the cursor is moved up a *count* lines.

Beginning of Line – 0 and ^

Syntax: ^
0

Function: Moves the cursor to the beginning of the current line. Note that 0 always moves the cursor to the first character of the current line. The caret (^) works somewhat differently: it moves to the first character on a line that is not a tab or a space. This is useful when editing files that have a great deal of indentation, such as program texts.

End of Line – \$

Syntax: \$

Function: Moves the cursor to the end of the current line. Note that the cursor resides on top of the last character on the line. If a count is given, the cursor is moved forward *count*–1 lines to the end of the line.

Goto Line – G

Syntax: [*linenumber*]G

Function: Moves the cursor to the beginning of the line specified by *linenumber*. If no *linenumber* is given, the cursor moves to the beginning of the *last* line in the file. To find the line number of the current line, use Ctrl-G.

Column - |

Syntax: `[column]|`

Function: Moves the cursor to the column in the current line given by *column*. If no *column* is given, the cursor is moved to the first column in the current line.

Word Forward - w and W

Syntax: `w`
`W`

Function: Moves the cursor forward to the beginning of the next word. The lowercase `w` command searches for a word defined as a string of alphanumeric characters separated by punctuation or whitespace (i.e., tab, newline, or space characters). The uppercase `W` command searches for a word defined as a string of nonwhitespace characters.

Back Word - b and B

Syntax: `b`
`B`

Function: Moves the cursor backward to the beginning of a word. The lowercase `b` command searches backward for a word defined as a string of alphanumeric characters separated by punctuation or whitespace (i.e., tab, newline, or space characters). The uppercase `B` command searches for a word defined as a string of nonwhitespace characters. If the cursor is already within a word, it moves backward to the beginning of that word.

End - e and E

Syntax: `e`
`E`

Function: Moves the cursor to the end of a word. The lowercase `e` command moves the cursor to the last character of a word, where a word is defined as a string of alphanumeric characters separated by punctuation or whitespace (i.e., tab, newline, or space characters). The uppercase `E` moves the cursor to the last character of a word where a word is defined as a string of nonwhitespace characters. If the cursor is already within a word, it moves to the end of that word.

Sentence - (and)

Syntax: ()

Function: Moves the cursor to the beginning (left parenthesis) or end of a sentence (right parenthesis). A sentence is defined as a sequence of characters ending with a period (.), question mark (?), or exclamation mark (!), followed by either two spaces or a newline. A sentence begins on the first nonwhitespace character following a preceding sentence. Sentences are also delimited by paragraph and section delimiters. See below.

Paragraph - { and }

Syntax: { }

Function: Moves the cursor to the beginning ({) or end (}) of a paragraph. A paragraph is defined with the *paragraphs* option. By default, paragraphs are delimited by the nroff macros ".IP", ".LP", ".P", ".QP", and ".bp". Paragraphs also begin after empty lines.

Section - [[and]]

Syntax:]] [[

Function: Moves the cursor to the beginning ([) or end (]) of a section. A section is defined with the *sections* option. By default, sections are delimited by the nroff macros ".NH" and ".SH". Sections also start at formfeeds (Ctrl-L) and at lines beginning with a brace ({).

Match Delimiter - %

Syntax: %

Function: Moves the cursor to a matching delimiter, where a delimiter is a parenthesis, a bracket, or a brace. This is useful when matching pairs of nested parentheses, brackets, and braces.

Home - H

Syntax: [*offset*]H

Function: Moves the cursor to the upper left corner of the screen. Use this command to quickly move to the top of the screen. If an *offset* is given, the cursor is homed *offset*-1

number of lines from the top of the screen. Note that the command “dH” deletes all lines from the current line to the top line shown on the screen.

Middle Screen – M

Syntax: M

Function: Moves the cursor to the beginning of the screen’s middle line. Use this command to quickly move to the middle of the screen from either the top or the bottom. Note that the command “dM” deletes from the current line to the line specified by the M command.

Lower Screen – L

Syntax: [*offset*]L

Function: Moves the cursor to the lowest line on the screen. Use this command to quickly move to the bottom of the screen. If an *offset* is given, the cursor is homed *offset*-1 number of lines from the bottom of the screen. Note that the command “dL” deletes all lines from the current line to the bottom line shown on the screen.

Previous Context – “ and “

Syntax: “
`character
“
`character

Function: Moves the cursor to previous context or to context marked with the m command. If the single quotation mark or back quotation mark is doubled, the cursor is moved to previous context. If a single character is given after either quotation mark, the cursor is moved to the location of the specified mark as defined by the m command. Previous context is the location in the file of the last “nonrelative” cursor movement. The single quotation mark (') syntax is used to move to the beginning of the line representing the previous context. The back quotation mark (`) syntax is used to move to the previous context *within* a line.

The Screen Commands

The screen commands are *not* cursor movement commands and cannot be used in delete commands as the delimiters of text objects. However, the screen commands do move the cursor and are useful in paging or scrolling through a file. These commands are described below:

Page — Ctrl-U and Ctrl-D

Syntax: *[size]*Ctrl-U
 *[size]*Ctrl-D

Function: Scrolls the screen up a half window (Ctrl-U) or down a half window (Ctrl-D). If *size* is given, the scroll is *size* number of lines. This value is remembered for all later scrolling commands.

Scroll — Ctrl-F and Ctrl-B

Syntax: Ctrl-F
 Ctrl-B

Function: Pages screen forward and backward. Two lines of continuity are kept between pages if possible. A preceding count gives the number of pages to move forward or backward.

Status — Ctrl-G

Syntax: BELL
 Ctrl-G

Function: Displays *vi* status on status line. This gives you the name of the file you are editing, whether it has been modified, the current line number, the number of lines in the file, and the percentage of the file (in lines) that precedes the cursor.

Zero Screen — z

Syntax: [*linenumber*]z[*size*]RETURN
 [*linenumber*]z[*size*].
 [*linenumber*]z[*size*]-

Function: Redraws the display with the current line placed at or “zeroed” at the top, middle, or bottom of the screen, respectively. If you give a *size*, the number of lines displayed is equal to *size*. If a preceding *linenumber* is given, the given line is placed at the top of the screen. If the last argument is a RETURN, the current line is placed at the top of the screen. If the last argument is a

period (.), the current line is placed in the middle of the screen. If the last argument is a minus sign (-), the current line is placed at the bottom of the screen.

Redraw – Ctrl-R or Ctrl-L

Syntax: Ctrl-R
 Ctrl-L

Function: Redraws the screen. Use this command to erase any system messages that may scramble your screen. Note that system messages do not affect the file you are editing.

Text Insertion

The text insertion commands always place you in insert mode. Exit from insert mode is always done by pressing ESC. The following insertion commands are “pure” insertion commands; no text is deleted when you use them. This differs from the text modification commands, change, replace, and substitute, which delete and then insert text in one operation.

Insert – i and I

Syntax: i[*text*]ESC
 I[*text*]ESC

Function: Insert *text* in editing buffer. The lowercase **i** command places you in insert mode. *Text* is inserted *before* the character beneath the cursor. To insert a newline, press a RETURN. Exit insert mode by typing the ESC key. The uppercase **I** command places you in insert mode, but begins text insertion at the beginning of the current line, rather than before the cursor.

Append – a and A

Syntax: a[*text*]ESC
 A[*text*]ESC

Function: Appends *text* to the editing buffer. The lowercase **a** command works exactly like the lowercase **i** command, except that text insertion begins after the cursor and not before. This is the one way to add text to the end of a line. The uppercase **A** command begins appending text at the end of the current line rather than after the cursor.

Open New Line – o and O

Syntax: o[*text*]ESC
 O[*text*]ESC

Function: Opens a new line and inserts text. The lowercase **o** command opens a new line below the current line; uppercase **O** opens a new line *above* the current line. After the new line has been opened, both these commands work like the **I** command.

Text Deletion

Many of the text deletion commands use the **D** key as an operator. This operator deletes text objects delimited by the cursor and a cursor movement command. Deleted text is always saved away in a buffer. The delete commands are described below:

Delete Character – x and X

Syntax: x
 X

Function: Deletes a character. The lowercase **x** command deletes the character beneath the cursor. With a preceding count, *count* characters are deleted to the right beginning with the character beneath the cursor. This is a quick and easy way to delete a few characters. The uppercase **X** command deletes the character just before the cursor. With a preceding count, *count* characters are deleted backward, beginning with the character just before the cursor.

Delete — d and D

Syntax: **d***cursor-movement*
dd
D

Function: Deletes a text object. The lowercase **d** command takes a *cursor-movement* as an argument. If the *cursor-movement* is an intraline command, deletion takes place from the cursor to the end of the text object delimited by the *cursor-movement*. Deletion forward deletes the character beneath the cursor; deletion backward does not. If the *cursor-movement* is a multi-line command, deletion takes place from and including the current line to the text object delimited by the *cursor-movement*.

The **dd** command deletes whole lines. The uppercase **D** command deletes from and including the cursor to the end of the current line.

Deleted text is automatically pushed on a stack of buffers numbered 1 through 9. The most recently deleted text is also placed in a special delete buffer that is logically buffer 0. This special buffer is the default buffer for all (put) commands using the double quotation mark (") to specify the number of the buffer for delete, put, and yank commands. The buffers 1 through 9 can be accessed with the **p** and **P** (put) commands by appending the double quotation mark (") to the number of the buffer. For example:

"4p

puts the contents of delete buffer number 4 in your editing buffer just below the current line. Note that the last deleted text is "put" by default and does not need a preceding buffer number.

Text Modification

The text modification commands all involve the replacement of text with other text. This means that some text will necessarily be deleted. All text modification commands can be "undone" with the **u** command:

Undo — u and U

Syntax: **u**
U

Function: Undoes the last insert or delete command. The lowercase **u** command undoes the last insert or delete command. This means that after an insert, **u** deletes text; and after a delete, **u** inserts text. For the purposes of undo, all text modification commands are considered insertions.

The uppercase U command restores the current line to its state before it was edited, no matter how many times the current line has been edited since you moved to it.

Repeat - .

Syntax: .

Function: Repeats the last insert or delete command. A special case exists for repeating the **p** and **P** "put" commands. When these commands are preceded by the name of a delete buffer, successive **u** commands display the contents of the delete buffers.

Change - c and C

Syntax: *ccursor-movement text* ESC
Ctext ESC
cctext ESC

Function: Changes a text object and replaces it with *text*. Text is inserted as with the **i** command. A dollar sign (\$) marks the extent of the change. The **c** command changes arbitrary text objects delimited by the cursor and a *cursor-movement*. The **C** and **cc** commands affect whole lines and are identical in function.

Replace - r and R

Syntax: *rchar*
Rtext ESC

Function: Overstrikes character or line with *char* or *text*, respectively. Use **r** to overstrike a single character and **R** to overstrike a whole line. A count multiplies the replacement text count times.

Substitute - s and S

Syntax: *s-text* ESC
S-text ESC

Function: Substitutes current character or current line with *text*. Use **s** to replace a single character with new text. Use **S** to replace the current line with new text. If a preceding count is given, *text* substitutes for count number of characters or lines depending on whether the command is **s** or **S**, respectively.

Filter — !

Syntax: **!*cursor-movement cmd* RETURN**

Function: Filters the text object delimited by the cursor and *cursor-movement* through the XENIX command, *cmd*. For example, the following command sorts all lines between the cursor and the bottom of the screen, substituting the designated lines with the sorted lines:

!Lsort

Arguments and shell metacharacters may be included as part of *cmd*; however, standard input and output are always associated with the text object being filtered.

Join Lines — J

Syntax: **J**

Function: Joins the current line with the following line. If a *count* is given, *count* lines are joined.

Shift — < and >

Syntax: **>[*cursor-movement*]**
<[*cursor-movement*]
>>
<<

Function: Shifts text left (>) or right (<). Text is shifted by the value of the option *shiftwidth*, which is normally set to eight spaces. Both the > and < commands shift all lines in the text object delimited by the current line and *cursor-movement*. The >> and << commands affect whole lines. All versions of the command can take a preceding count that acts to multiply the number of objects affected.

Text Movement

The text movement commands move text in and out of the named buffers *a-z* and out of the delete buffers *1-9*. These commands either “yank” text out of the editing buffer and into a named buffer or “put” text into the editing buffer from a named buffer or a delete buffer. By default, text is put and yanked from the “unnamed buffer”, which is also where the most recently deleted text is placed. Thus it is quite reasonable to delete text, move your cursor to the location where you want the deleted text placed, and then put the text back into the editing buffer at this new location with the **p** or **P** command.

The named buffers are most useful for keeping track of several chunks of text that you want to keep on hand for later access, movement, or rearrangement. These buffers are named with the letters *a* through *z*. To refer to one of these buffers (or one of the numbered delete buffers) in a command, use a quotation mark. For example, to yank a line into the buffer named *a*, enter:

```
"ayy
```

To put this text back into the file, enter:

```
"ap
```

If you delete text in the buffer named *A* rather than *a*, text is appended to the buffer.

Note that the contents of the named buffers are not destroyed when you switch files. Therefore, you can delete or yank text into a buffer, switch files, and then do a put. Buffer contents are *destroyed* when you exit the editor, so be careful.

Put — p and P

Syntax: ["*alphanumeric*]**p**
 ["*alphanumeric*]**P**

Function: Puts text from a buffer into the editing buffer. If no buffer name is specified, text is put from the unnamed buffer. The lowercase **p** command puts text either below the current line or after the cursor, depending on whether the buffer contains a partial line or not. The uppercase **P** command puts text either above the current line or before the cursor, again depending on whether the buffer contains a partial line or not.

Yank – y and Y

Syntax: `["letter"]ycursor-movement`
`["letter"]yy`
`["letter"]Y`

Function: Copies text in the editing buffer to a named buffer. If no buffer name is specified, text is yanked into the unnamed buffer. If an uppercase *letter* is used, text is appended to the buffer and does not overwrite and destroy the previous contents. When a *cursor-movement* is given as an argument, the delimited text object is yanked. The **Y** and **yy** commands yank a single line, or, if a preceding count is given, multiple lines can be yanked.

Searching

The search commands search either forward or backward in the editing buffer for text that matches a given regular expression.

Search – / and ?

Syntax: `/[pattern]/[offset]RETURN`
`/[pattern]RETURN`
`?[pattern]?[offset]RETURN`
`?[pattern]RETURN`

Function: Searches forward (/) or backward (?) for *pattern*. A string is actually a regular expression. The trailing delimiter is not required. If no *pattern* is given, then last *pattern* searched for is used. After the second delimiter, an *offset* may be given, specifying the beginning of a line relative to the line on which *pattern* was found. For example:

`/word/-`

finds the beginning of the line immediately preceding the line containing "word" and the following command:

`/word/+2`

finds the beginning of the line two lines after the line containing "word". See also the *ignorecase* and *magic* options.

Next String – n and N

Syntax: **n**
 N

Function: Repeats the last search command. The **n** command repeats the search in the same direction as the last search command. The **N** command repeats the search in the opposite direction of the last search command.

Find Character – f and F

Syntax: **fchar**
 Fchar
 ;
 ,

Function: Finds character *char* on the current line. The lowercase **f** searches forward on the line; the uppercase **F** searches backward. The semicolon (**;**) repeats the last character search. The comma (**,**) reverses the direction of the search.

To Character – t and T

Syntax: **tchar**
 Tchar
 ;
 ,

Function: Moves the cursor up to but not on *char*. The semicolon (**;**) repeats the last character search. The comma (**,**) reverses the direction of the search.

Mark – m

Syntax: **mletter**

Function: Marks a place in the file with a lowercase *letter*. You can move to a mark using the “to mark” commands described below. It is often useful to create a mark, move the cursor, and then delete from the cursor to the mark “a” with the following command:

d’a

To Mark — ' and `

Syntax: *'letter*
`letter

Function: Move to *letter*. These commands let you move to the location of a mark. Marks are denoted by single lower-case alphabetic characters. Before you can move to a mark, it must first be created with the **m** command. The back quotation mark (```) moves you to the exact location of the mark within a line; the forward quotation mark (`'`) moves you to the beginning of the line containing the mark. Note that these commands are also legal cursor movement commands.

Exit and Escape Commands

There are several commands that are used to escape from *vi* command mode and to exit the editor. These are described in the following section.

ex Escape - :

Syntax: :

Function: Enters *ex* escape mode to execute an *ex* command. The colon appears on the status line as a prompt for an *ex* command. You then can enter an *ex* command line terminated by either a RETURN or an ESC and the *ex* command will execute. You are then prompted to type RETURN to return to *vi* command mode. During the input of the *ex* command line or during execution of the *ex* command, you may press INTERRUPT to stop what you are doing and return to *vi* command mode.

Exit Editor - ZZ

Syntax: ZZ

Function: Exit *vi* and write out the file if any changes have been made. This returns you to the shell from which you started *vi*.

Quit to ex - Q

Syntax: Q

Function: Enters the *ex* editor. When you do this, you will still be editing the same file. You can return to *vi* by entering the *vi* command from *ex*.

ex Commands

Entering the colon (:) escape command when in command mode produces a colon prompt on the status line. This prompt is for a command available in the line-oriented editor, *ex*. In general, *ex* commands let you write out or read in files, escape to the shell, or switch editing files.

Many of these commands perform actions that affect the “current” file by default. The current file is normally the file that you named when you started *vi*, although the current file can be changed with the “file” command, *f*, or with the “next” command, *n*. In most respects, these commands are identical to similar commands for the editor, *ed*. All such *ex* commands are aborted by either RETURN or ESC. We shall use RETURN in our examples. Command entry is terminated by typing INTERRUPT.

Command Structure

Most *ex* command names are English words, and initial prefixes of the words are acceptable abbreviations. In descriptions, only the abbreviation is discussed, since this is the most frequently used form of the command. The ambiguity of abbreviations is resolved in favor of the more commonly used commands. As an example, the command **substitute** can be abbreviated *s*, while the shortest available abbreviation for the **set** command is *se*.

Most commands accept prefix addresses specifying the lines in the file that they are to affect. A number of commands also may take a trailing *count* specifying the number of lines to be involved in the command. Counts are rounded down if necessary. Thus, the command “10p” displays the tenth line in the buffer while “move 5” moves the current line after line 5.

Some commands take other information or parameters, stated after the command name. Examples might be option names in a **set** command, such as “set number”, a filename in an **edit** command, a regular expression in a **substitute** command, or a target address for a **copy** command. For example:

1,5 copy 25

A number of commands have variants. The variant form of the command is invoked by placing an exclamation mark (!) immediately after the command name. Some of the default variants may be controlled by options; in this case, the exclamation mark turns off the meaning of the default.

In addition, many commands take flags, including the characters “p” and “l”. A “p” or “l” must be preceded by a blank or tab. In this case, the command abbreviated by these characters is executed after the command completes. Since *ex* normally displays the new current line after each change, *p* is rarely necessary. Any number of plus (+) or minus (-) characters may also be given with these flags. If they appear, the specified offset is applied to the current line value before the printing command is executed.

Most commands that change the contents of the editor buffer give feedback if the scope of the change exceeds a threshold given by the **report option**. This feedback helps to detect undesirably large changes so that they may be quickly and easily reversed with the **undo** command. After commands with global effect, you will be informed if the net change in the number of lines in the buffer during this command exceeds this threshold.

Command Addressing

The following specifies the line addressing syntax for *ex* commands:

.	The current line. Most commands leave the current line as the last line which they affect. The default address for most commands is the current line, thus “.” is rarely used alone as an address.
<i>n</i>	The <i>n</i> th line in the editor’s buffer, lines being numbered sequentially from 1.
\$	The last line in the buffer.
%	An abbreviation for “1,\$”, the entire buffer.
+ <i>n</i> or - <i>n</i>	An offset, <i>n</i> relative to the current buffer line. The forms “.+3” “+3” and “+++” are all equivalent. If the current line is line 100 they all address line 103.

/pattern/ or *?pattern?*

Scan forward and backward respectively for a text matching the regular expression given by *pattern*. Scans normally wrap around the end of the buffer. If all that is desired is to print the next line containing *pattern*, the trailing slash (/) or question mark (?) may be omitted. If *pattern* is omitted or explicitly empty, the string matching the last specified regular expression is located. The forms “RETURN” and “?RETURN” scan using the last named regular expression. After a substitute, “RETURN” and “??RETURN” would scan using that substitute’s regular expression.

“ or ‘x

Before each nonrelative motion of the current line dot (.), the previous current line is marked with a label, subsequently referred to with two single quotation marks (“”). This makes it easy to refer or return to this previous context. Marks are established with the *vi m* command, using a single lowercase letter as the name of the mark. Marked lines are later referred to with the following notation:

‘x.

where *x* is the name of a mark.

Addresses to commands consist of a series of addresses, separated by a colon (:) or a semicolon (;). Such address lists are evaluated left to right. When addresses are separated by a semicolon (;) the current line (.) is set to the value of the previous addressing expression before the next address is interpreted. If more addresses are given than the command requires, all but the last one or two are ignored. If the command takes two addresses, the first addressed line must precede the second in the buffer. Null address specifications are permitted in a list of addresses, the default in this case is the current line “.”; thus “.,100” is equivalent to “.,100”. It is an error to give a prefix address to a command which expects none.

Command Format

The following is the format for all *ex* commands:

[*address*] [*command*] [!] [*parameters*] [*count*] [*flags*]

All parts are optional depending on the particular command and its options. The following section describes specific commands.

Argument List Commands

The argument list commands allow you to work on a set of files, by remembering the list of filenames that are specified when you invoke *vi*. The **args** command lets you examine this list of filenames. The **file** command gives you information about the current file. The **n** (next) command lets you either edit the next file in the argument list or change the list. And the **rewind** command lets you restart editing the files in the list. All of these commands are described below:

args The members of the argument list are displayed, with the current argument delimited by brackets. For example, a list might look like this:

file1 file2 [file3] file4 file5

The current file is *file3*.

- f** Displays the current filename, whether it has been modified since the last **w**rite command, whether it is read-only, the current linenumber, the number of lines in the buffer, and the percentage of the buffer that you have edited. In the rare case that the current file is "[Not edited]", this is noted also; in this case you have to use **w!** to write to the file, since the editor is not sure that a **w** command will not destroy a file unrelated to the current contents of the buffer.
- f file** The current filename is changed to *file* which is considered "[Not edited]".
- n** The next file in the command line argument list is edited.
- n!** This variant suppresses warnings about the modifications to the buffer not having been written out, discarding irretrievably any changes that may have been made.
- n [+command] filelist** The specified *filelist* is expanded and the resulting list replaces the current argument list; the first file in the new list is then edited. If *command* is given (it must contain no spaces), then it is executed after editing the first such file.
- rew** The argument list is rewound, and the first file in the list is edited.
- rew!** Rewinds the argument list discarding any changes made to the current buffer.

Edit Commands

To edit a file other than the one you are currently editing, you will often use one of the variations of the **e** command.

In the following discussions, note that the name of the current file is always remembered by **vi** and is specified by a percent sign (%). The name of the *previous* file in the editing buffer is specified by a number sign (#).

The edit commands are described below:

- e *file*** Used to begin an editing session on a new file. The editor first checks to see if the buffer has been modified since the last **w** command was issued. If it has been, a warning is issued and the command is aborted. The command otherwise deletes the entire contents of the editor buffer, makes the named file the current file, and displays the new filename. After ensuring that this file is sensible, (i.e., that it is not a binary file, directory, or a device), the editor reads the file into its buffer. If the read of the file completes without error, the number of lines and characters read is displayed on the status line. If there were any non-ASCII characters in the file, they are stripped of their non-ASCII high bits, and any null characters in the file are discarded. If none of these errors occurred, the file is considered edited. If the last line of the input file is missing the trailing newline character, it is supplied and a complaint issued. The current line is initially the first line of the file.
- e! *file*** This variant form suppresses the complaint about modifications having been made and not written from the editor buffer, thus discarding all changes that have been made before editing the new file.
- e +*n file*** Causes the editor to begin editing at line *n* rather than at the first line. The argument *n* may also be an editor command containing no spaces; for example, “+/pattern”.
- Ctrl-^** This is a shorthand equivalent for “:e #RETURN”, which returns to the previous position in the last edited file. If you do not want to write the file, you should use “:e! #RETURN” instead.

Write Commands

The write commands let you write out all or part of your editing buffer to either the current file or to some other file. These commands are described below:

- w *file*** Writes changes made back to *file*, displaying the number of lines and characters written. Normally, *file* is omitted and the buffer is written to the name of the current file. If *file* is specified, text is written to that file. The editor writes to a file only if it is the current file and is edited, or if the file does not exist. Otherwise, you must give the variant form **w!** to force the write. If the file does not exist it is created. The

current filename is changed only if there is no current filename; the current line is never changed.

If an error occurs while writing the current and edited file, the editor displays:

No write since last change

even if the buffer had not previously been modified.

w>> *file* Appends the buffer contents at the end of an existing file. Previous file contents are not destroyed.

w! *name* Overrides the checking of the normal **write** command, and writes to any file that the system permits.

w !*command* Writes the specified lines into *command*. Note the difference between

w! *file*

which overrides checks and

w !*cmd*

which writes to a command. The output of this command is displayed on the screen and not inserted in the editing buffer.

Read Commands

The read commands let you read text into your editing buffer at any location you specify. The text you read in must be at least one line long, and can be either a file or the output from a command.

r *file* Places a copy of the text of the given file in the editing buffer after the specified line. If no file is given, the current filename is used. The current filename is not changed unless there is none, in which case the file becomes the current name. If the file buffer is empty and there is no current name, this is treated as an **e** command.

Address 0 is legal for this command and causes the file to be read at the beginning of the buffer. Statistics are given as for the **e** command when the **r** successfully terminates. After an **r** the current line is the last line read.

r !command Reads the output of *command* into the buffer after the specified line. A blank or tab before the exclamation mark (!) is mandatory.

Quit Commands

There are several ways to exit *vi*. Some abort the editing session, some write out the editing buffer before exiting, and some warn you if you decide to exit without writing out the buffer. All of these ways of exiting are described below:

- q** Exits *vi*. No automatic write of the editor buffer to a file is performed. However, *vi* displays a warning message if the file has changed since the last **w** command was issued, and does not quit. *vi* also displays a diagnostic if there are more files in the argument list left to edit. Normally, you will wish to save your changes, and you should enter a **w** command. If you wish to discard them, enter the **q!** command variant.
- q!** Quits from the editor, discarding changes to the buffer without complaint.
- wq name** Like a **w** and then a **q** command.
- wq! name** Overrides checking normally made before execution of the **w** command to any file. For example, if you own a file but do not have write permission turned on, the **wq!** allows you to update the file anyway.
- x name** If any changes have been made and not written, writes the buffer out and then quits. Otherwise, it just quits.

Global and Substitute Commands

The global and substitute commands allow you to perform complex changes to a file in a single command. Learning how to use these commands is a must for an experienced *vi* user.

g/pattern/cmds

The **g** command has two distinct phases. In the first phase, each line matching *pattern* in the editing buffer is marked. Next, the given command list is executed with the current line, dot (.), initially set to each marked line.

The command list consists of the remaining commands on the current input line and may continue to multiple lines by ending all but the last such line with a backslash (\). This multiple-line option will not work from within

vi, you must switch to *ex* to do it. If *cmds* (or the trailing slash (/) delimiter) is omitted, each line matching *pattern* is displayed.

The **g** command itself may not appear in *cmds*. The options **autoprint** and **autoindent** are inhibited during a global command and the value of the **report** option is temporarily infinite, in deference to a **report** for the entire global. Finally, the context mark (') or (`) is set to the value of the current line (.) before the global command begins and is not changed during a global command.

The following global commands, most of them substitutions, cover the most frequent uses of the global command.

- | | |
|------------------------|---|
| g/s1/p | This command simply prints all lines that contain the string "s1". |
| g/s1/s//s2/ | This command substitutes the <i>first</i> occurrence of "s1" on all lines that contain it with the string "s2". |
| g/s1/s//s2/g | This command substitutes all occurrences of "s1" with the string "s2". This includes multiple occurrences of "s1" on a line. |
| g/s1/s//s2/gp | This command works the same as the preceding example, except that in addition, all changed lines are displayed on the screen. |
| g/s1/s//s2/gc | This command prompts you to confirm that you want to make each substitution of the string "s1" with the string "s2". If you enter a Y, the given substitution is made, otherwise it is not. |
| g/s0/s/s1/s2/g | This command marks all those lines that contain the string "s0", and then for those lines only, substitutes all occurrences of the string "s1" with "s2". |
| g!/pattern/cmds | This variant form of g runs <i>cmds</i> at each line not matching <i>pattern</i> . |

s/pattern/repl/options

On each specified line, the first instance of text matching the regular expression *pattern* is replaced by the replacement text *repl*. If the **global** indicator option character **g** appears, all instances on a line are substituted. If the **confirm** indication character **c** appears, before each substitution the line to be substituted is printed on the screen with the

string to be substituted marked with caret (^) characters. By entering Y, you cause the substitution to be performed; any other input causes no change to take place. After an s command, the current line is the last line substituted.

v/pattern/cmds A synonym for the **global** command variant **g!**, running the specified *cmds* on each line that does not match *pattern*.

Text Movement Commands

The text movement commands are largely superseded by commands available in vi command mode. However, the following two commands are still quite useful:

co addr flags A copy of the specified lines is placed after *addr*, which may be "0". The current line "." addresses the last line of the copy.

[range]maddr The **m** command moves the lines specified by *range* after the line given by *addr*. For example, **m+** swaps the current line and the following line, since the default range is just the current line. The first of the moved lines becomes the current line (dot).

Shell Escape Commands

You will often want to escape from the editor to execute normal XENIX commands. You may also want to change your working directory so that your editing can be done with respect to a different working directory. These operations are described below:

cd directory The specified *directory* becomes the current directory. If no directory is specified, the current value of the *home* option is used as the target directory. After a **cd**, the current file is not considered to have been edited so that write restrictions on preexisting files still apply.

sh A new shell is created. You may invoke as many commands as you like in this shell. To return to *vi*, enter a Ctrl-D to terminate the shell.

!command The remainder of the line after the exclamation (!) is sent to a shell to be executed. Within the text of *command*, the characters "%" and "#" are expanded as the filenames of the current file and the last edited file and the character "!" is replaced

with the text of the previous command. Thus, in particular, “!!” repeats the last such shell escape. If any such expansion is performed, the expanded line is echoed. The current line is unchanged by this command.

If there has been “[No write]” of the buffer contents since the last change to the editing buffer, a diagnostic is displayed before the command is executed as a warning. A single exclamation (!) is displayed when the command completes.

Other Commands

The following command descriptions explain how to use miscellaneous *ex* commands that do not fit into the above categories:

abbr Maps the first argument to the following string. For example, the following command

```
:abbr rainbow yellow green blue red
```

maps “rainbow” to “yellow green blue red”. Abbreviations can be turned off with the **unabbreviate** command, as in:

```
:una rainbow
```

map, map!

Maps any character or escape sequence to an existing command sequence. Characters mapped with **map!** work in both command and insert mode, while characters mapped with **map** work only in command mode. Characters mapped with **map!** cannot be unmapped using **unmap**.

nu Displays each specified line preceded by its buffer line number. The current line is left at the last line displayed. To get automatic line numbering of lines in the buffer, set the *number* option.

preserve The current editor buffer is saved as though the system had just crashed. This command is for use only in emergencies when a **w** command has resulted in an error and you do not know how to save your work.

= Displays the line number of the addressed line. The current line is unchanged.

recover file

Recovers *file* from the system save area. The system saves a copy of the editing buffer only if you have made

changes to the file, the system crashes, or you execute a **preserve** command. When you use **preserve**, you are notified by mail when a file is saved.

set argument

With no arguments, **set** displays those options whose values have been changed from their defaults; with the argument **all**, it displays all of the option values.

Giving an option name followed by a question mark (?) causes the current value of that option to be displayed. The question mark is unnecessary unless the option is a Boolean value. Switch options are given values either with:

set option

to turn them on or:

set nooption

to turn them off. String and numeric options are assigned with:

set option=value

More than one parameter may be given to **set**; all are interpreted from left to right.

tag label

The focus of editing switches to the location of *label*. If necessary, *vi* will switch to a different file in the current directory to find *label*. If you have modified the current file before giving a **tag** command, you must first write it out. If you give another **tag** command with no argument, the previous *label* is used.

Similarly, if you press Ctrl-], *vi* searches for the word immediately after the cursor as a tag. This is equivalent to entering “:tag”, the word following the cursor, and then pressing the RETURN key.

The tags file is normally created by a program such as **ctags**, and consists of a number of lines with three fields separated by blanks or tabs. The first field gives the name of the tag, the second the name of the file where the tag resides, and the third gives an addressing form which can be used by the editor to find the tag. This field is usually a contextual scan using */pattern/* to be immune to minor changes in the file. Such scans are always performed as if the **nomagic** option was set. The tag names in the tags file must be sorted alphabetically. There are a number of options that can be set to affect the *vi* environment. These can be set with the **ex set** command either while editing or immediately after *vi* is invoked in the *vi* start-up file, **.exrc**.

unmap

Unmaps any character or escape sequence that has been mapped using the map command.

The first thing that must be done before you can use *vi*, is to set the terminal type so that *vi* understands how to talk to the particular terminal you are using.

Each time *vi* is invoked, it reads commands from the file named **.exrc** in your home directory. This file normally sets the user's preferred options so that they need not be set manually each time you invoke *vi*. Each of the options is described in detail below.

Options

There are only two kinds of options: switch options and string options. A switch option is either on or off. A switch is turned off by prefixing the word *no* to the name of the switch within a **set** command. String options are strings of characters that are assigned values with the syntax *option=string*. Multiple options may be specified on a line. *vi* options are listed below:

autoindent, ai default: **noai**

Can be used to ease the preparation of structured program text. For each line created by an append, change, insert, open, or substitute operation, *vi* looks at the preceding line to determine and insert an appropriate amount of indentation. To back the cursor up to the preceding tab stop, press Ctrl-D. The tab stops going backward are defined as multiples of the **shiftwidth** option. You cannot backspace over the indent, except by pressing Ctrl-D.

Specially processed in this mode is a line with no characters added to it, which turns into a completely blank line (the whitespace provided for the **autoindent** is discarded). Also, specially processed in this mode are lines beginning with a caret (^) and immediately followed by a Ctrl-D. This causes the input to be repositioned at the beginning of the line, but retains the previous indent for the next line. Similarly, a "0" followed by a Ctrl-D, repositions the cursor at the beginning without retaining the previous indent. **Autoindent** doesn't happen in global commands.

autoprint ap default: **ap**

Causes the current line to be displayed after each *ex* **copy**, **move**, or **substitute** command. This has the same effect as supplying a trailing "p" to each such command. **Autoprint** is suppressed in globals, and only applies to the last command on a line.

autowrite, aw default: **noaw**

Causes the contents of the buffer to be automatically written to the current file if you have modified it when you give a **next**, **rewind**, **tag**, or **!** command, or a Ctrl-^ (switch files) or Ctrl-] (tag go to) command.

beautify, bf default: **nobeautify**

Causes all control characters except tab, newline and formfeed to be discarded from the input. A complaint is registered the first time a backspace character is discarded. **Beautify** does not apply to command input.

directory, dir default: **dir=/tmp**

Specifies the directory in which **vi** places the editing buffer file. If the directory does not have write permission, the editor will exit abruptly when it fails to write to the buffer file.

edcompatible default: **noedcompatible**

Causes the presence or absence of **g** and **c** suffixes on substitute commands to be remembered, and to be toggled on and off by repeating the suffixes. The suffix **r** causes the substitution to be like the tilde (~) command, instead of like the ampersand command (&).

errorbells, eb default: **noeb**

Error messages are preceded by a bell. If possible, the editor always places the error message in inverse video instead of ringing the bell.

hardtabs, ht default: **ht=8**

Gives the boundaries on which terminal hardware tabs are set or on which tabs the system expands.

ignorecase, ic default: **noic**

Maps all uppercase characters in the text to lowercase in regular expression matching. In addition, all uppercase characters in regular expressions are mapped to lowercase except in character class specifications enclosed in brackets.

lisp default: **nolisp**

Autoindent indents appropriately for LISP code, and the () { } [[and]] commands are modified to have meaning for LISP.

list default: **nolist**

All printed lines are displayed,, showing tabs and end-of-lines.

magic default: **magic**

If **nomagic** is set, the number of regular expression metacharacters is greatly reduced, with only up-arrow (^) and dollar sign (\$) having special effects. In addition, the metacharacters “~” and “&” in replacement patterns are treated as normal characters. All the normal metacharacters may be made **magic** when

nomagic is set by preceding them with a backslash (\).

mesg default: **nomesg**

Causes write permission to be turned off to the terminal while you are in visual mode, if **nomesg** is set. This prevents people writing to your screen with the XENIX **write** command and scrambling your screen as you edit.

number, n default: **nonumber**

Causes all output lines to be printed with their line numbers.

open default: **open**

If set to **noopen**, the commands **open** and **visual** are not permitted from **ex**. This is set to prevent confusion resulting from accidental entry to open or visual mode.

optimize, opt default: **optimize**

Output of text to the screen is expedited by setting the terminal so that it does not perform automatic carriage returns when displaying more than one line of output, thus greatly speeding output on terminals without addressable cursors when text with leading whitespace is printed.

paragraphs, para default: **para=IPLPPPQPP TPbp**

Specifies paragraph delimiters for the { and } operations. The pairs of characters in the option's value are the names of the nroff macros that start paragraphs.

prompt default: **prompt**

ex input is prompted for with a colon (:). If **noprompt** is set, when **ex** command mode is entered with the **Q** command, no colon prompt is displayed on the status line.

redraw default: **noredraw**

The editor simulates (using great amounts of output), an intelligent terminal on a dumb terminal. Useful only at very high speed.

remap default: **remap**

If on, mapped characters are repeatedly tried until they are unchanged. For example, if *o* is mapped to *O* and *O* is mapped to *I*, *o* will map to *I* if **remap** is set, and to *O* if **noremap** is set.

report default: **report=5**

Specifies a threshold for feedback from commands. Any command that modifies more than the specified number of lines will provide feedback as to the scope of its changes. For global commands and the undo command, the net change in the number of lines in the buffer is presented at the end of the command. Thus notification is suppressed during a **g** command on the individual commands performed.

scroll default: **scroll=1/2 window**

Determines the number of logical lines scrolled when Ctrl-D is received from a terminal input in command mode, and the number of lines displayed by a command mode **z** command (double the value of *scroll*).

sections default: **sections=SHNHH HU**

Specifies the section macros for the **[[** and **]]** operations. The pairs of characters in the option's value are the names of the nroff macros that start paragraphs.

shell, sh default: **sh=/bin/sh**

Gives the pathname of the shell forked for the shell escape command (**!**), and by the **shell** command. The default is taken from SHELL in the environment, if present.

shiftwidth, sw default: **sw=8**

Gives the width of a software tab stop, used in reverse tabbing with Ctrl-D when using **autoindent** to append text, and by the shift commands.

showmatch, sm default: **nosm**

When a **)** or **}** is typed, moves the cursor to the matching **(** or **{** for one second if this matching character is on the screen.

tabstop, ts default: **ts=8**

The editor expands tabs in the input file to be on *n* boundaries for the purposes of display.

taglength, tl default: **tl=0**

The first *n* characters in a tag name are significant, but all others are ignored. A value of zero (the default) means that all characters are significant.

tags default: **tags=tags /usr/lib/tags**

A path of files to be used as tag files for the **tag** command. A requested tag is searched for in the specified files, sequentially. By default, files named *tag* are searched for in the current directory and in **/usr/lib**.

term default=value of shell TERM variable

The terminal type of the output device.

terse default: **noterse**

Shorter error diagnostics are produced for the experienced user.

warn default: **warn**

Warn if there has been "[No write since last change]" before a shell escape command (**!**).

window default: **window = speed dependent**

This specifies the number of lines in a text window. The default is 8 at slow speeds (600 baud or less), 16 at medium speed (1200 baud), and the full screen (minus one line) at higher speeds.

w300, w1200, w9600

These are not true options but set **window** (above) only if the speed is slow (300), medium (1200), or high (9600), respectively.

wrapscan, ws default: **ws**

Searches, using the regular expressions in addressing, will wrap around past the end of the file.

wrapmargin, wm default: **wm=0**

Defines the margin for automatic insertion of newlines during text input. A value of zero specifies no wrap margin.

writeany, wa default: **nowa**

Inhibits the checks normally made before **write** commands, allowing a write to any file that the system protection mechanism will allow.

Regular Expressions

A regular expression specifies a set of strings of characters. A member of this set of strings is said to be "matched" by the regular expression. *vi* remembers two previous regular expressions: the previous regular expression used in a substitute command and the previous regular expression used elsewhere, referred to as the previous *scanning* regular expression. The previous regular expression can always be referred to by a null regular expression: e.g., *"/"* or *"?"*.

The regular expressions allowed by *vi* are constructed in one of two ways depending on the setting of the **magic** option. The *ex* and *vi* default setting of **magic** gives quick access to a powerful set of regular expression metacharacters. The disadvantage of **magic** is that the user must remember that these metacharacters are **magic** and precede them with the backslash (\) to use them as "ordinary" characters. With **nomagic** set, regular expressions are much simpler, there being only two metacharacters. The power of the other metacharacters is still available by preceding the now ordinary character with a "\". Note that "\" is always a metacharacter. In this discussion, the **magic** option is assumed. With **nomagic**, the only special characters are the caret (^) at the beginning of a regular expression, the dollar sign (\$) at the end of a regular expression, and the backslash (\). The tilde (~) and the ampersand (&) also lose their special meanings related to the replacement pattern of a substitute.

The following basic constructs are used to construct **magic** mode regular expressions.

char An ordinary character matches itself. Ordinary characters are any characters except a caret (^) at the beginning of a line, a dollar sign (\$) at the end of line, a star (*) as any character other than the first, and any of the following characters:

. \ [~

These characters must be preceded by a backslash (\) if they are to be treated as ordinary characters.

- ^ At the beginning of a pattern, forces the match to succeed only at the beginning of a line.
- \$ At the end of a regular expression, forces the match to succeed only at the end of the line.
- . Matches any single character except the newline character.
- \< Forces the match to occur only at the beginning of a "word"; that is, either at the beginning of a line, or just before a letter, digit, or underline and after a character not one of these.
- \> Similar to "\<", but matching the end of a "word", i.e., either the end of the line or before a character which is not a letter, a digit, or the underline character.

[*string*]

Matches any single character in the class defined by *string*. Most characters in *string* define themselves. A pair of characters separated by a dash (-) in *string* defines the set of characters between the specified lower and upper bounds, thus "[a-z]" as a regular expression matches any single lowercase letter. If the first character of *string* is a caret (^) then the construct matches those characters which it otherwise would not. Thus "[^a-z]" matches anything but a lowercase letter or a newline. To place any of the characters caret, left bracket, or dash in *string* they must be escaped with a preceding backslash (\).

The concatenation of two regular expressions first matches the leftmost regular expression and then the longest string that can be recognized as a regular expression. The first part of this new regular expression matches the first regular expression and the second part matches the second. Any of the single character matching regular expressions mentioned above may be followed by a star (*) to form a regular expression that matches zero or more adjacent occurrences of the characters matched by the prefixing regular expression. The tilde (~) may be used in a regular expression to match the text that defined the replacement part of the last s

command. A regular expression may be enclosed between the sequences “\ (“ and “\)” to remember the text matched by the enclosed regular expression. This text can later be interpolated into the replacement text using the following notation:

`\digit`

where *digit* enumerates the set of remembered regular expressions.

The basic metacharacters for the replacement pattern are the ampersand (&) and the tilde (~); these are given as “\&” and “\~” when **nomagic** is set. Each instance of the ampersand is replaced by the characters matched by the regular expression. In the replacement pattern, the tilde stands for the text of the previous replacement pattern.

Other metasequences possible in the replacement pattern are always introduced by a backslash (\). The sequence “\n” is replaced by the text matched by the *n*th regular subexpression enclosed between “\ (“ and “\)”. When nested, parenthesized subexpressions are present, *n* is determined by counting occurrences of “\ (“ starting from the left. The sequences “\u” and “\l” cause the immediately following character in the replacement to be converted to uppercase or lowercase, respectively, if this character is a letter. The sequences “\U” and “\L” turn such conversion on, either until “\E” or “\e” is encountered, or until the end of the replacement pattern.

Limitations

When using *vi*, you should note the following limits:

- 250K lines in a file

- 510 characters per line

- 256 characters per global command list

- 128 characters per filename

- 128 characters in the previous inserted and deleted text

- 100 characters in a shell escape command

- 63 characters in a string valued option

- 30 characters in a tag name

Credit

This utility was developed at the University of California at Berkeley and is used with permission.

Notes

The

program can be used to restore *vi* buffer files that were lost as a result of a system crash. The program searches the **/tmp** directory for *vi* buffer files and places them in the directory **/usr/preserve**. The owner can retrieve these files using the **-r** option.

The

program must be placed in the system startup file, **/etc/rc**, before the command that cleans out the **/tmp** directory. See the XENIX *Operations Guide* for more information on **/etc/rc**.

Name

vsh - menu driven visual shell

Syntax

vsh

Description

vsh is a highly interactive, visually oriented shell which eases many XENIX activities. The *vsh* features both standard and customizable XENIX command menus and on-line help. The *vsh* displays information and menus in windows on the screen. To enter *vsh*, simply enter:

vsh

from a shell prompt. *vsh* can also be made a user's default shell by changing their shell entry in */etc/passwd* (the last colon-separated field). Help is available from all menus by typing the question mark character.

The very last line of the screen is a status line. The status line displays the current pathname, the date, time and operating system name. If you have new mail, the status line will indicate so. Above the status line is the message line, which displays messages, error or otherwise, from *vsh*.

A command menu is displayed at the bottom of the screen. The standard menu contains a range of commonly used XENIX commands. Above the command menu is the output window. This window contains a scrolling display of the output from commands. This window is not visible at start-up, but is displayed while running certain commands such as '='.

In the top of the screen is a window with a listing of the current working directory. To alter the size of this window, use the *Window* command from the main command menu. Items in the listing window may be selected using standard key commands (q.v.). Two special key commands are used with the listing window. The equals sign '=' ('SHOW') key, displays the contents of the currently selected file or directory. The minus sign '-' ('GOAWAY') key, returns you to the listing window.

Commands may be invoked in one of two ways. A command can be selected by pressing the first letter of its name. Alternatively, press the space bar. Each time the space bar is pressed, the next menu item is highlighted. This highlighting indicates that the command has been selected. Backspace moves to the previous selection.

Once a command is selected, press the return key. A menu is displayed which gives the valid arguments for the particular command. The default choice is shown in parentheses, e.g.:

recursive: Yes (No)

To send the output to another program, you may enter a vertical bar in the "output:" field of the commands' menu.

When the menu is filled in, press RETURN to start the command.

Main Menu Commands

The following menu options are available from the standard main menu. Certain sub-commands are available under the Options selection. These are described in the next section.

Copy

Copy a file to a new file. Copy the contents of a directory to a new directory.

Delete

Delete a file or directory.

Edit

Invoke an editor for a file. Default is the visual editor vi(C).

Help

Get help on diverse topics. A menu is displayed at the bottom of the screen of available help topics.

Mail

Send or read XENIX mail.

Name

Rename a directory or file.

Options

Perform various commands. See OPTIONS section.

Print

Print file or files on systems' lineprinter.

Quit

Quit the visual shell.

Run

Run a specified XENIX command or applications program.

View

View a specified file or directory listing. This file or directory listing will be displayed in the upper window. Use the *vsh* scrolling commands to move around (see KEY COMMANDS Section).

Window

Reset upper window 'redraw' characteristics and height.

Options Subcommand

The Options selection on the main menu has several important commands grouped under the selections Directory, Filesystem, Output, and Permissions. These are as follows:

Directory**Make**

Make a directory under current working directory.

Usage

Display disk usage by number of blocks in current working directory.

Filesystem**Create**

Create a filesystem.

FilesCheck

Check file system consistency.

Mount

Mount a file system on a specified mount-point.

SpaceFree

Report number of disk blocks available on all or some mounted file systems.

Unmount

Unmount specified file system if it is not currently busy.

Output

VShell

Echo vsh commands in output window (default).

XENIX

Echo actual XENIX commands in output window. For instance, if running "Options Filesystem FilesCheck", the command *fsck* will be displayed in the output window if "Options Output Xenix" is set.

Permissions

Change permissions on a file or directory.

Key Commands

The following keyboard commands allow editing of menus and fields, and give access to various vsh features.

<Ctrl-E>

Move the cursor up one line.

<Ctrl-X>

Move the cursor down one line.

<Ctrl-S>

Move the cursor left one character.

<Ctrl-D>

Move the cursor right one character.

<Ctrl-R> <Ctrl-E>

Scroll page up.

<Ctrl-R> <Ctrl-X>

Scroll page down.

<Ctrl-R> <Ctrl-S>

Scroll page left.

<Ctrl-R> <Ctrl-D>

Scroll page right.

<Ctrl-Q>

Home. Go to start of menu.

- <Ctrl-Z>
End. Go to the end of menu.
- <Ctrl-C>
Cancel. Stop present operation and return to the main command menu.
- <RETURN>
Start the present command.
- <TAB>, <Ctrl-I>, or <Ctrl-A>
Move to and select entire contents of next field in command line.
- <SPACE>
Select next item in menu.
- <BACKSPACE> or <Ctrl-H>
Select previous menu item. In editing command lists, deletes character. Replacement text may then be typed.
- <Ctrl-Y> or
Delete selected character.
- <Ctrl-L>
Move to next character to right of current cursor position.
- <Ctrl-K>
Move to next character to left of current cursor position.
- <Ctrl-P>
Move to next word to right of current cursor position.
- <Ctrl-O>
Move to next word to left of current cursor position.
- ? Help. Request information about the selected command or command in progress at the time of the request.
- = Show. Display sub-directory listings and text files in directory listings. Display submenus for commands in main menu.
- Goaway. Return listing window to current or parent directory after a show command.
- @ Display the Modify menu.
- ! Redraw the screen.
- | Display filter menu.

Files

menu.def	standard menu definition file.
.mnu	extension for customized command menus.
/usr/lib/vsh/VSHELL.HPP	help file
/usr/lib/vsh/VSHELL.HPT	yet another help file

Name

wait – Awaits completion of background processes.

Syntax

wait

Description

Waits until all background processes started with an ampersand (&) have finished, and reports on abnormal terminations.

Because the *wait*(S) system call must be executed in the parent process, the shell itself executes *wait*, without creating a new process.

See Also

sh(C)

Notes

Not all the processes of a pipeline with three or more stages are children of the shell, and thus cannot be waited for.

Name

wall – Writes to all users.

Syntax

/etc/wall

Description

wall reads a message from the standard input until an end-of-file. It then sends this message to all users currently logged in preceded by “Broadcast Message from ...”. *wall* is used to warn all users, for example, prior to shutting down the system.

The sender should be super-user to override any protections the users may have invoked.

Files

/dev/tty*

See Also

mesg(C), write(C)

Diagnostics

Cannot send to ... The open on a user’s tty file has failed.

Name

`wc` – Counts lines, words and characters.

Syntax

`wc [-lwc] [names]`

Description

`wc` counts lines, words and characters in the named files, or in the standard input if no *names* appear. It also keeps a total count for all named files. A word is a maximal string of characters delimited by spaces, tabs, or newlines.

The options **l**, **w**, and **c** may be used in any combination to specify that a subset of lines, words, and characters are to be reported. The default is **-lwc**.

When *names* are specified on the command line, they are printed along with the counts.

Name

what – Identifies files.

Syntax

what files

Description

what searches the given files for all occurrences of the pattern *@(#)* and prints out what follows until the first tilde (~), greater-than sign (>), new-line, backslash (\) or null character. The SCCS command *get*(CP) substitutes this string as part of the *@(#)* string.

For example, if the shell procedure in file **print** contains

```
# @(#)this is the print program
# @(#)syntax: print [files]
pr $* |lpr
```

then the command

```
what print
```

displays the name of the file **print** and the identifying strings in that file:

```
print:
      this is the print program
      syntax: print [files]
```

what is intended to be used with the *get*(CP) command, which automatically inserts identifying information, but it can also be used where the information is inserted manually.

See Also

admin(CP), get(CP)

Name

who - Lists who is on the system.

Syntax

who [-uTHldtasq] [file]

who am i

who am I

Description

who can list the user's name, terminal line, login time, and the elapsed time since activity occurred on the line; it also lists the process ID of the command interpreter (shell) for each current XENIX system user. It examines the */etc/utmp* file to obtain its information. If *file* is given, that file is examined. Usually, *file* will be */etc/wtmp*, which contains a history of all the logins since the file was last created.

who with the **am i** or **am I** option identifies the invoking user.

Except for the default **-s** option, the general format for output entries is:

name [state] line time activity pid [comment] [exit]

With options, *who* can list logins, logoffs, reboots, and changes to the system clock, as well as other processes spawned by the *init* process. These options are:

- u** This option lists only those users who are currently logged in. The *name* is the user's login name. The *line* is the name of the line as found in the directory */dev*. The *time* is the time that the user logged in. The *activity* is the number of hours and minutes since activity last occurred on that particular line. A dot (.) indicates that the terminal has seen activity in the last minute and is therefore "current". If more than twenty-four hours have elapsed or the line has not been used since boot time, the entry is marked old. This field is useful when trying to determine whether a person is working at the terminal or not. The *pid* is the process ID of the user's shell. The *comment* is the comment field. It can contain information about where the terminal is located, the telephone number of the dataset, the type of terminal if hard-wired, etc.

- T This option is the same as the **-u** option, except that the *state* of the terminal line is printed. The *state* describes whether someone else can write to that terminal. A plus character (+) appears if the terminal is writable by anyone; a minus character (-) appears if it is not. **Root** can write to all lines having a plus character (+) or a minus character (-) in the *state* field. If a bad line is encountered, a question mark (?) is displayed.
- l This option lists only those lines on which the system is waiting for someone to login. The *name* field is **LOGIN** in such cases. Other fields are the same as for user entries except that the *state* field does not exist.
- H This option displays column headings above the regular output.
- q This is a quick *who*, displaying only the names and the number of users currently logged on. When this option is used, all other options are ignored.
- d This option displays all processes that have expired and have not been respawned by *init*. The *exit* field appears for dead processes and contains the termination and exit values (as returned by *wait(S)*), of the dead process. This can be useful in determining why a process terminated.
- t This option indicates the last change to the system clock (via the *date(C)* command) by **root**. See *su(C)*.
- a This option processes the */etc/utmp* file or the named *file* with all options turned on.
- s This option is the default and lists only the *name*, *line*, and *time* fields.

Files

/etc/utmp
/etc/wtmp

See Also

date(C), *login(C)*, *mesg(C)*, *su(C)*, *utmp(F)*, *wait(S)*

Name

whodo – Determines who is doing what.

Syntax

/etc/whodo

Description

whodo produces merged, reformatted, and dated output from the *who*(C) and *ps*(C) commands.

See Also

ps(C), *who*(C)

Name

`write` – Writes to another user.

Syntax

`write user [tty]`

Description

`write` copies lines from your terminal to that of another user. When first called, it sends the message:

Message from *your-logname* *your-tty* ...

The recipient of the message should write back at this point. Communication continues until an end-of-file is read from the terminal or an interrupt is sent. At that point, `write` displays:

(end of message)

on the other terminal and exits.

If you want to write to a user who is logged in more than once, the *tty* argument may be used to indicate the appropriate terminal.

Permission to write may be denied or granted by use of the `mesg(C)` command. At the outset, writing is allowed. Certain commands, in particular `nroff(CT)` and `pr(C)`, disallow messages in order to prevent messy output.

If the character `!` is found at the beginning of a line, `write` calls the shell to execute the rest of the line as a command.

The following protocol is suggested for using `write`: when you first write to another user, wait for him or her to write back before starting to send. Each party should end each message with a distinctive signal (`(o)` for “over” is conventional), indicating that the other may reply; `(oo)` for “over and out” is suggested when conversation is to be terminated.

WRITE (C)

WRITE (C)

Files

/etc/utmp	To find user
/bin/sh	To execute !

mail(C), mesg(C), who(C)

Name

xargs – Constructs and executes commands.

Syntax

xargs [*flags*] [*command* [*initial-arguments*]]

Description

xargs combines the fixed *initial-arguments* with arguments read from the standard input to execute the specified *command* one or more times. The number of arguments read for each *command* invocation and the manner in which they are combined are determined by the flags specified.

Command, which may be a shell file, is searched for using the shell **\$PATH** variable. If *command* is omitted, **/bin/echo** is used.

Arguments read in from standard input are defined to be contiguous strings of characters delimited by one or more blanks, tabs, or newlines; empty lines are always discarded. Blanks and tabs may be embedded as part of an argument if escaped or quoted: Characters enclosed in quotes (single or double) are taken literally, and the delimiting quotes are removed. Outside of quoted strings, a backslash (\) will escape the next character.

Each argument list is constructed starting with the *initial-arguments*, followed by some number of arguments read from standard input (exception: see **-i** flag). Flags **-i**, **-l**, and **-n** determine how arguments are selected for each command invocation. When none of these flags are coded, the *initial-arguments* are followed by arguments read continuously from standard input until an internal buffer is full, and *command* is executed with the accumulated args. This process is repeated until there are no more args. When there are flag conflicts (e.g., **-l** vs. **-n**), the last flag has precedence. *Flag* values are:

-l*number* *Command* is executed for each *number* lines of nonempty arguments from the standard input. This is instead of the default single line of input for each *command*. The last invocation of *command* will be with fewer lines of arguments if fewer than *number* remain. A line is considered to end with the first newline *unless* the last character of the line is a blank or a tab; a trailing blank/tab signals continuation through the next nonempty line. If *number* is omitted, 1 is assumed. Option **-x** is forced.

- ireplstr** Insert mode: *command* is executed for each line from the standard input, taking the entire line as a single arg, inserting it in *initial-arguments* for each occurrence of *replstr*. A maximum of 5 arguments in *initial-arguments* may each contain one or more instances of *replstr*. Blanks and tabs at the beginning of each line are thrown away. Constructed arguments may not grow larger than 255 characters, and option **-x** is also forced. **{ }** is assumed for *replstr* if not specified.
- nnumber** Executes *command* , using as many standard input arguments as possible, up to the *number* of arguments maximum. Fewer arguments are used if their total size is greater than *size* characters, and for the last invocation if there are fewer than *number* arguments remaining. If option **-x** is also coded, each *number* of arguments must fit in the *size* limitation, or *xargs* terminates execution.
- t** Trace mode: The *command* and each constructed argument list are echoed to file descriptor 2 just prior to their execution.
- p** Prompt mode: The user is prompted whether to execute *command* at each invocation. Trace mode (**-t**) is turned on to display the command instance to be executed, followed by a **?...** prompt. A reply of **y** (optionally followed by anything), will execute the command; anything else, including a carriage return, skips that particular invocation of *command*.
- x** Causes *xargs* to terminate if any argument list would be greater than *size* characters; **-x** is forced by the options **-i** and **-l**. When neither of the options **-i**, **-l**, or **-n** are coded, the total length of all arguments must be within the *size* limit.
- ssize** The maximum total size of each argument list is set to *size* characters; *size* must be a positive integer less than or equal to 470. If **-s** is not coded, 470 is taken as the default. Note that the character count for *size* includes one extra character for each argument and the count of characters in the command name.
- eofstr** *Eofstr* is taken as the logical end-of-file string. Underscore (**_**) is assumed for the logical EOF string if **-e** is not coded. **-e** with no *eofstr* coded turns off the logical EOF string capability (underscore is taken literally). *xargs* reads standard input until either end-of-file or the logical EOF string is encountered.

xargs terminates if it either receives a return code of **-1** from, or if it cannot execute, *command*. When *command* is a shell program, it should explicitly *exit* (see *sh*(C)) with an appropriate value to avoid accidentally returning with **-1**.

Examples

The following will move all files from directory \$1 to directory \$2, and echo each move command just before doing it:

```
ls $1 | xargs -i -t mv $1/{ } $2/{ }
```

The following will combine the output of the parenthesized commands onto one line, which is then echoed to the end of file *log*:

```
(logname; date; echo $0 $*) | xargs >>log
```

The user is prompted to enter which files in the current directory are to be printed and prints them one at a time:

```
ls | xargs -p -l lpr
```

Or many at a time:

```
ls | xargs -p -l | xargs lpr
```

The following will execute *diff*(C) with successive pairs of arguments originally entered as shell arguments:

```
echo $* | xargs -n2 diff
```

Name

yes – Prints string repeatedly.

Syntax

yes [*string*]

Description

yes repeatedly outputs “y”, or if a single string argument is given, *arg* is output repeatedly. The command will continue indefinitely unless aborted. Useful in pipes to commands that prompt for input and require a “y” response for a yes. In this case, *yes* terminates when the command it pipes to terminates, so that no infinite loop occurs.

Name

intro – Introduction to miscellaneous features and files.

Description

This section contains miscellaneous information useful in maintaining the system. Included are descriptions of files, devices, tables and programs that are important in maintaining the entire system.

Name

aliases, aliases.hash, malias, malias.hash, faliases - Micnet aliasing files.

Description

These files contain the alias definitions for a Micnet network. Aliases are short names or abbreviations that may be used in the *mail* command to refer to specific machines or users in a network. Aliasing allows a complex combination of site, machine, and user names to be represented by a single name.

The *aliases*, *malias*, and *faliases* files each define a different type of alias. The *aliases* file defines the standard aliases which are names for specific systems and users and, in some case, for commands. The *malias* file defines machine aliases, names, and paths for specific systems. The *faliases* file defines forwarding aliases which are temporary names for forwarding mail intended for one system or user to another.

The *aliases.hash* file is the hashed version of the *aliases* file created by the *aliashash* command. The file is used by the *mail* command to resolve all standard aliases and is identical to the *aliases* file except for a hash table at the beginning of the file. The hash table allows for more efficient access to the entries in the file. The *aliases* file need only be present to generate the *aliases.hash* file. The *aliases* file is not required to run the network.

The *malias.hash* file is the hashed version of the *malias* file. It is an optional file created by executing the following command:

```
/usr/lib/mail/aliashash /usr/lib/mail/malias
```

If the *malias.hash* file is created, *malias* is no longer necessary to run the network. If the number of machines in the network is large, and particularly if several types of networks are in use, it is recommended that the *malias* file be hashed. In such a network, the configuration is no longer homogeneous, aliases are likely to be fairly complex and machine aliases are likely to differ between machines. The use of machine aliases allows the standard alias file to be identical on all machines in the network. In such an environment, *netutil* can only generate network files that can be used as a starting point. The rest of the network maintenance should be done manually with a text editor.

Each file contains zero or more lines. If hashing is to be performed, at least one alias is required. Each line lists the alias and its meaning. The alias meaning can have site, machine, and user

login names and other aliases (its exact composition depends on the type of alias). A colon (:) separating the alias and meaning is required.

In the **aliases** file, a line can have the forms:

```
alias:[[site!]]machine:]user,[[site!]]machine:]user]...
```

```
alias:[[site!]]machine:]command-pipeline
```

```
alias:error-message
```

Site and *machine* are the site and machine names of the system to which the user belongs or on which the specified command is to be executed. The site and machine names must end with an exclamation mark (!) or colon (:) respectively, and must be defined in a **systemid** file. A machine alias may be used in place of a site and machine name if it is followed by a question mark.

User is a user login name or another alias. User names in a list must be separated by commas. A newline may immediately follow a comma. Spaces and tabs are allowed, but only immediately before or after a comma or newline.

Command-pipeline is any valid command (with necessary arguments) preceded by a pipe symbol (|) and enclosed in double quotation marks. Spaces may separate the command and arguments, but there must be no space between the first double quotation mark and the pipe symbol.

Error-message is any sequence of letters, numbers, and punctuation marks (except a double quotation mark), preceded by a number sign (#) and enclosed in double quotation marks.

In the **faliases** file, each line can have the same form as lines in the **aliases** file except that no more than one user name can be given for any one alias. To prevent alias expansion on a remote machine, the meaning should be escaped with "\\", as in:

```
foo: mach?\foo
```

Failure to do the escape may result in an infinite forwarding loop. If this happens and the loop does not invoke a **uucp** connection, looping will be detected, and the mail will be returned to the sender.

The **alias.hash** file has already been searched at this point. If there is no explicit machine given as part of the meaning, the recipient will be assumed to be local. After forward aliasing is complete, machine aliasing is performed as necessary.

In the **malias** file, a line has the form:

```
alias:[[site!]machine:]...
```

Site and *machine* are the site and machine names for a specific network and system. Multiple site and machine names direct messages along the specified path of systems. If no site or machine name is given, the alias is ignored.

Before the *mail* program sends a message, it searches the **aliases.hash**, **faliases**, and **malias** files to see if any of the names given with the command are aliases. Each file is searched in turn (**aliases.hash**, **faliases**, then **malias**) and if a match is found, the alias is replaced with its meaning. If no match is found, the name is assumed to be the valid login name of a user on that machine. The search in the **aliases.hash** file continues until all aliases have been replaced, so it is possible for several replacements to occur for a single name. Alias loops are now detected. If a loop exists, any recipients involved in the alias loop are dropped from the mail recipient list, and an error message is displayed. The **faliases** file is searched once, from beginning to end, even if it is empty. The **malias** file is searched only if the alias contains a machine alias.

When an alias is a user or a list of users, the *mail* command sends the message to each user in the list. When it is a command-pipeline, the *mail* command starts execution of the command on the specified machine and sends the message as input. When the alias is an error-message, the *mail* command ignores the message and instead, displays the alias and its meaning at the standard error.

In all files, any line beginning with a number sign (#) is considered a comment and is ignored.

As a special feature, any alias that contains a site name as the first component of its meaning is automatically prepended with the machine alias **uucp?**. This alias may be explicitly defined in the **malias** file to help direct mail between networks to the system performing the *uucp* link.

Directives

Though alias directives are never included in an alias expansion, they can be used to restrict the expansion to a class of users, forward the unexpanded alias to another machine, or produce error messages. An **aliases** file may include directives of the form:

```
testalias: $xalaska, mikem, georger, terih
```

```
sams: "$e ambiguous, use samst or samsm"
```

Fields on the right-hand side of an alias (after the colon) that begin with a dollar sign (\$) character, are alias directives. Fields containing any blanks or tabs must be enclosed in quotes. The directive must precede all normal right-hand fields as shown in the example above. The character following the dollar sign (\$) specifies the directive type:

\$n <real name or description>

\$x <machine>

\$e <error message>

\$p <permissions>

\$r <restrictions>

None of the above directives are currently supported in `/usr/lib/mail/faliases`. Only the \$e is supported in `/usr/lib/mail/maliases` and `maliases.hash`. Unrecognized directives do not create error messages and are treated as if they do not exist. The above directives are described in detail as follows:

- \$n For a user alias, this field should contain the full real name of the user associated with the alias. For a group alias, a description of the group should be given.
- \$x Causes the alias to be forwarded, unexpanded, to the machine specified in this field. White space is only allowed immediately following the \$x. Since machine aliasing will be performed, the appropriate machine alias must exist in the `maliases` file.
- \$e This field contains an error message to be printed. The left side of the alias will be removed from the list of users to be aliased. An alternate form of \$e is #.
- \$p This field contains the character star (*) or a string of upper and lowercase alphabetic characters. Each character indicates that the user on the left-hand side of the alias belongs to a special "class" of users. The star (*) character implies membership in all such classes.
- \$r This field contains a string of upper and lower case alphabetic characters, each character indicating a "class" of users to be granted expansion permission. The absence of a \$r field means that any user can expand the alias. If the \$r field exists, expansion is only allowed if:
 - 1) the user requesting expansion has a \$p field and it contains one or more of the characters found in the \$r field.

- 2) the user has a \$p field and it contains a “*”.
- 3) the real user ID is 0 (super user).

If expansion is not allowed, no error messages result; the alias in question is treated as if it were not present.

To send mail delivery problems to root, the following alias could be used:

network: “\$n the network mail recipient,” root

To forward a group alias called *testalias* to a machine called *alaska* and expand it there, the following alias may be used:

testalias: \$xalaska, mikem, georger, terih

/usr/lib/mail/faliases

/usr/lib/mail/maliases.hash

See Also

aliashash(M), netutil(C), systemid(M), top(M)

Name

aliashash – Micnet alias hash table generator.

Syntax

aliashash [-v] [-o output-file] [input-file]

Description

The *aliashash* command reads the *input-file* and generates an *output-file* containing a hash table of alias definitions for a Micnet network. The *input-file* must name a file containing alias definitions in the form described for the *aliases* file (see *aliases*(M)). If the *-o* option is not used to specify an *output-file*, the command creates a file with the same name as the *input-file* but with *.hash* appended to it. If no *input-file* is given, the command reads the file named */usr/lib/mail/aliases* and creates the file named */usr/lib/mail/aliases.hash*.

If invoked with the *-v* option, the command lists information about the hash table.

The *output-file* will contain both the alias definitions given in the *input-file* and the new hash table. The hash table appears at the beginning of the file and is separated from the alias definitions by a blank line. The hash table has three or more lines. The first line is:

```
#<hash>
```

The second line has 4 entries: the bytes per table entry, the maximum number of items per hash value, the number of entries in the table, and the offset (in bytes) from the beginning of the file to the beginning of the alias definitions.

The next lines (up to the end of the hash table) contain the hash table entries. Each line has 8 entries (separated by spaces) and each entry has 2 fields. The first field (1 byte) is a checksum (represented as a printable character); the second field is a pointer (in bytes) to the alias definition. The pointer is represented as a hexadecimal number with leading blanks if necessary and is always relative to the start of the definitions.

The *aliashash* command is normally invoked by the *install* option of the *netutil* command. If the alias definitions of a network must be changed, the definitions in the *aliases* file should be changed and a new *aliases.hash* file created using the *aliashash* command. The new *aliases.hash* file must then be copied to all other computers in the network.

Files

/usr/lib/mail/aliashash
/usr/lib/mail/aliases
/usr/lib/mail/aliases.hash
/usr/lib/mail/maliases.hash

See Also

aliases(M), netutil(C)

Warning

Do not use the *aliashash* command to create the **aliases.hash** file while the network is running. If necessary, create a temporary output file, **aliases.hash-**, using the **-o** option, then enter:

```
mv aliases.hash- aliases.hash
```

This will prevent disruption of the network.

Name

ascii – Map of the ASCII character set.

Description

ascii is a map of the ASCII character set. It lists both octal and hexadecimal equivalents of each character. It contains:

ASCII (M)

ASCII (M)

Files

`/usr/pub/ascii`

Name

autoboot – Automatically boots the system.

Description

The system can be set up to go through the *boot* stages automatically when the computer is turned on (booted). If the XENIX system is configured to *autoboot*, and as long as no key is pressed, *init* (M)'s behavior is controlled via the *-a* flag passed by the kernel causing XENIX to time out after about 30 seconds at each stage of the *boot*(M) procedure. However, if any key is pressed, the *autoboot* process stops, requiring the user to continue entering information at each stage.

The *boot* procedure checks the file */etc/default/boot* for instructions on autobooting. The line:

AUTO=

is set to one of the following three conditions:

NEVER The system never *autoboots*. The user is required to enter appropriate responses at each step of the *boot* procedure. However, the system will autoboot to the point of needing user input, generally as far as *fsck*(C), where it will stop and wait.

CLEAN The system *autoboots*. However, if the root filesystem is corrupted, because the system was *shutdown*(C) improperly, *fsck*(C) is invoked. If the root filesystem needs modification, the *autoboot* procedure stops and waits for the user to enter responses to the *fsck* queries. If the root filesystem needs no modification, *autoboot* continues *booting* the system. Other filesystems are checked, cleaned, and mounted as specified in */etc/rc*.

DIRTY The system always *autoboots*. If the root filesystem is corrupted, *fsck* is invoked using the *-rr* option, which recovers the root filesystem. The *-rr* option to *fsck* causes the system to be *shutdown* if modifications are made to the root filesystem. See *fsck*(C) for more information.

A scratch file is needed by *fsck* to check large filesystems. The user is informed during the installation of XENIX if the system needs a scratch file to *fsck* the root filesystem. If necessary, the installation

procedure creates the filesystem **/dev/scratch** to write the *fsck* temporary file. *fsck* uses the file named on the **/etc/default/boot** line:

SCRATCH=

as a scratch file. If the installation procedure creates the scratch filesystem, the entry in the **/etc/default/boot** is automatically made.

SCRATCH need only be specified if the root filesystem is large enough to need a temporary file. If a file is specified, it is always passed to *fsck*, when checking the root filesystem, even if the system is *booted* manually. The only exception is the first time XENIX is booted from the hard disk, when the user must specify the scratch file. The file specified as **SCRATCH** must not be on the filesystem being checked by *fsck*. **SCRATCH** also can not be on an unmounted filesystem.

If the XENIX mail system, *mail*(C), is installed on the system, the output of the boot sequence is mailed to *root*. Otherwise, the system administrator should check the file **/etc/bootlog** for the boot sequence output. The output of *fsck*(C) is temporarily saved in the file **/dev/recover** before it is moved to **/etc/bootlog** and finally may be sent to the system administrator via *mail*.

Files

/etc/bootlog	<i>boot</i> output log for autobooting systems
/etc/default/boot	boot information file
/etc/rc	instructions for entering multi-user mode, includes mounting and checking additional file systems
/dev/recover	allows saving of <i>fsck</i> output
/dev/scratch	temporary <i>fsck</i> file for large filesystems

See Also

boot(M), **fsck**(C), **init**(M)

Notes

The utilities invoked during the *boot* procedure time out only when the system *autoboots*. For example, *asktime*(C) times out after 30 seconds when the system *autoboots*, but waits for a response from the user any other time it is invoked (for example, during *boot* or from the command line).

Name

badtrk – Scans fixed disk for flaws and creates flaw map

Syntax

badtrk -f /dev/rhd*

Description

Used chiefly during system installation, *badtrk* scans the media surface for flaws, creates a new bad track table, prints the current table, and adds and deletes entries to the table.

To use *badtrk*, you must be in single user mode. (See *shutdown(C)*). Once in single user mode, enter:

badtrk -f /dev/rhd0a

to address the primary fixed disk. Or enter:

badtrk -f /dev/rhd1a

to address the secondary fixed disk.

Usage

When *badtrk* is executed, the program first displays the main menu:

1. Print Current Bad Track Table
2. Scan Media Surface for Possible Flaws
3. Create New Bad Track Table
4. Add entries to Current Bad Track Table by Head/Cylinder #
5. Add entries to Current Bad Track Table by Block Number
6. Delete Entries From Bad Track Table

You are prompted for option numbers, and, depending upon the option, more information may be entered.

Entering “q” at the main menu quits the *badtrk* program. Whenever you enter the quit command, *badtrk* asks if the changes which were made (if there are any) should be saved.

The only way to correct erroneous table entries is to return to the main *badtrk* menu, then select option “6” to delete the entries.

A bad track table (option "1") might look like this:

Defective Track Table			
Number	Cylinder	Head	Sector
1.	190	3	12971-12987

Option "2" scans the disk for flaws. The scanning process takes roughly one to two minutes per megabyte of storage on the disk.

As the program finds flawed tracks, it displays the location of each bad track. An example error message might be:

error on dev Fixed Disk (0/47), block=12954 cmd=0003 status=0018
sector = 12971, cylinder/head = 190/3

(You may see this kind of message if there is a read error during the scanning procedure.)

When the scan is complete, the main menu reappears. The program automatically enters any detected flaws in the bad track table.

If you do not have a bad track table, and a scan does not reveal any flaws, but you disk is furnished with a flaw map, you can enter these flaws into a bad track table. Select either option "4" or "5" to add the entries (see next paragraph).

To add flaw locations to an existing bad track table, select either option "4" or option "5" depending upon the format of the flaw map furnished with your disk. Enter the defective tracks, one per line. When you are finished making changes to the flaw table, enter: q and press RETURN to return to the main menu.

Notes

This utility can only be used in single user mode.

If a bad spot develops in inode table or superblock, reinstallation is required.

Files

/etc/badtrk

Name

clock – The system real-time (time of day) clock.

Description

The **clock** file provides access to the battery-powered, real-time time of day clock. Reading this file returns the current time; writing to the file sets the current time. The time, 10 bytes long, has the following form:

MMddhhmmyy

where *MM* is the month, *dd* is the day, *hh* is the hour, *mm* is the minute, and *yy* is the last two digits of the year. For example, the time:

082615035 is 15:03 on August 26, 1985.

Files

/dev/clock

See Also

setclock(M)

Notes

Not all computers have battery-powered real-time time of day clocks. Refer to your computer's hardware reference manual.

Name

daemon.mn – Micnet mailer daemon

Syntax

/usr/lib/mail/daemon.mn [-ex]

Description

The mailer daemon performs the “backend” networking functions of the *mail*, *rcp*, and *remote* commands by establishing and servicing the serial communication link between computers in a Micnet network.

When invoked, the daemon creates multiple copies of itself, one copy for each serial line used in the network. Each copy opens the serial line, creates a startup message for the LOG file, and waits for a response from the daemon at the other end. The startup message lists the names of the machines to be connected, the serial line to be used, and the current date and time. If the daemon receives a correct response, it establishes the serial link and adds the message “first handshake complete” to the LOG file. If there is no response, the daemon waits indefinitely.

If invoked with the *-x* switch, the daemon records each transmission in the LOG file. A transmission entry shows the direction of the transmission (tx for transmit, rx for receive), the number of bytes transmitted, the elapsed time for the transmission (in minutes and seconds), and the time of day of the transmission (in hours, minutes, and seconds). Each entry has the form:

direction byte_count elapsed_time time_of_day

The daemon also records the date and time every hour. The date and time have the same format as described for the *date* command.

If invoked with the *-e* switch, the daemon records all transmission errors in the LOG file. An error entry shows the cause of the error preceded by the name of the daemon subroutine which detected the error.

The mailer daemon is normally invoked by the *start* option of the *netutil* command and is stopped by the *stop* option.

During the normal course of execution, the mailer daemon uses several files in the */usr/spool/micnet/remote* directory. These files provide storage for LOG entries, commands issued by the *remote(C)* command, and a list of processes under daemon control.

Files

/usr/lib/mail/daemon.mn
/usr/spool/micnet/remote/*/LOG
/usr/spool/micnet/remote/*/mn
/usr/spool/micnet/remote/local/mn*
/usr/spool/micnet/remote/lock
/usr/spool/micnet/remote/pids

See Also

netutil(C)

Name

default – Default program information directory.

Description

The files in the directory **/etc/default** contain the default information used by system commands such as **backup(C)** and **remote(C)**. Default information is any information required by the command that is not explicitly given when the command is invoked.

The directory may contain zero or more files. Each file corresponds to one or more commands. A command searches a file whenever it has been invoked without sufficient information. Each file contains zero or more entries which define the default information. Each entry has the form:

keyword

or

keyword=value

where *keyword* identifies the type of information available and *value* defines its value. Both *keyword* and *value* must consist of letters, digits, and punctuation. The exact spelling of a *keyword* and the appropriate *values* depend on the command and are described with the individual commands.

Any line in a file beginning with a number sign (#) is considered a comment and is ignored.

Files

/etc/default/backup

/etc/default/boot

/etc/default/cron

/etc/default/dumpdir

/etc/default/login

/etc/default/lpd

/etc/default/micnet

/etc/default/mkuser

/etc/default/msdos

/etc/default/passwd

/etc/default/restor

/etc/default/tar

See Also

backup(C), boot(HW), cron(M), dos(C), dumpdir(C), login(M),
lpr(C), micnet (M), mkuser(C), pwadmin(C), remote(C),
restore(C), su(C), tar(C)

Note

Not all commands use */etc/default* files. Please refer to the manual page for a specific command to determine if */etc/default* files are used, and what information is specified.

Name

dial - Dials a modem.

Syntax

/usr/lib/uucp/dial ttyname telno speed

Description

/usr/lib/uucp/dial dials a modem is attached to *ttyname*. Although the installed dialer program is a compiled "C" program, you can also create a shell script to perform dialing functions.

uucp(C) uses */usr/lib/uucp/dial*. The *uucp* dialup timeout is now sufficient to allow *uucp* to dial long distance numbers on pulse dial telephone lines. The distributed program is for the Hayes® Smartmodem 1200 or Hayes Smartmodem 1200B. There is also a program in */usr/lib/uucp*, **dialVADIC** which dials a Racal-Vadic 3450. For other auto dial modems, the program must be rewritten and compiled.

uucp(C) invokes *dial*, with a *ttyname*, *telno* (phone number), and *speed*. *dial* attempts to dial the phone number on the specified line at the given speed. The *dial* program provided also logs each attempted call that fails in */usr/spool/uucp/LOGFILE*.

The following is an example C program for a Hayes Smartmodem. This program is not part of the distribution and is included as an example. It will not make entries in the *uucp* **LOGFILE**.

```
/*
 * %Z% %M% %I% %D% %Q%
 *
 * Copyright (C) Microsoft Corporation, 1983
 *
 * Simple dialer program for the Hayes "Smart" Modem 1200
 *
 * See Hayes manual for command definitions
 *
 * Usage: dial ttyname telnumber speed
 *
 * returns 0 if a connection was made
 *       -1 otherwise
 */
```

```

#include <stdio.h>
#include <signal.h>
#include <fcntl.h>
#include <sys/types.h>
#include <sys/ioctl.h>
#include <termio.h>

#define SAME    0
char *setup = "M1 F1 DT"; /* Speaker on, Full Duplex, Touch tone */
struct termio term;
int baudrate; /* baud rate of modem */
char buffer[80];
int alrmint();

main(argc,argv)
int argc;
char *argv[];
{
    FILE *fdr,*fdw;
    int fd;

    if( argc != 4 ) {
        fprintf(stderr,"Usage: dial devicename number speed\n");
        exit(-1);
    }
    if( (fd=open(argv[1],O_RDWR|O_NDELAY)) < 0 ) {
        fprintf(stderr,"dial: Can't open device: %s for reading.\n", argv[1]);

}
exit(0);
}

alrmint()
{
    exit(-1);
}

```

You can copy and modify the file `/usr/lib/uucp/dial.c` or the above program example to use your modem. There is a makefile in `/usr/lib/uucp` which should be modified for the new dialer, and can be used to compile the new program.

If you create a *dial* program for another modem, send us the source. User generated *dial* programs will be considered for inclu-

sion in future releases.

Files

/usr/lib/uucp/dial	Dialer program used by uucp
/usr/lib/uucp/dial.c	C source program for <i>dial</i>
/usr/lib/uucp/dialVADIC	Racal Vadic 3450 dialer
/usr/lib/uucp/makefile	Makefile to compile and link new <i>dial</i>
/usr/spool/uucp/LOGFILE	Uucp log file

See Also

dial(S), uucp(C), uux(C)

Notes

You must have the XENIX Development System installed in order to compile and install a new *dial* program.

Name

environ – The user environment.

Description

The user environment is a collection of information about a user, such as his login directory, mailbox, and terminal type. The environment is stored in special “environment variables,” which can be assigned character values, such as names of files, directories, and terminals. These variables are automatically made available to programs and commands invoked by the user. The commands can then use the values to access the user’s files and terminal.

The following is a short list of commonly used environment variables.

PATH	Defines the search path for the directories containing commands. The system searches these directories whenever a user types a command without giving a full pathname. The search path is one or more directory names separated by colons (:). Initially, PATH is set to <code>:/bin:/usr/bin</code> .
HOME	Names the user’s login directory. Initially, HOME is set to the login directory given in the user’s <code>passwd</code> file entry.
TERM	Defines the type of terminal being used. This information is used by commands such as <code>more(C)</code> which rely on information about the capabilities of the user’s terminal. The variable may be set to any valid terminal name (see <code>terminals(M)</code>) directly or by using the <code>tset(C)</code> command.
TZ	Defines time zone information. This information is used by <code>date(C)</code> to display the appropriate time. The variable may have any value of the form <code>xxxnzzz</code> where <code>xxx</code> is standard local time zone abbreviation, <code>n</code> is the difference in hours from GMT, and <code>zzz</code> is the daylight-saving local time zone abbreviation (if any). For example, <code>EST5EDT</code> . Refer to the <code>tz(M)</code> manual page for more on <code>TZ</code> .
HZ	Defines, with a numerical value, the check interrupts per second. The value of this variable is dependent on the hardware, and configured in the file <code>etc/default/login</code> . If <code>HZ</code> is not defined, programs which depend on this hertz value, such as <code>prof(CP)</code> and <code>times(S)</code> , will not run.

The environment can be changed by assigning a new value to a variable. For Bourne shell, *sh(C)*, an assignment has the following format:

name=value

For example, the assignment:

TERM=h29

sets the TERM variable to the value "h29". The new value can be "exported" to each subsequent invocation of a shell by exporting the variable with the *export* command (see *sh(C)*) or by using the *env(C)* command.

C-shell users make assignments using the *setenv* command. For example: *setenv TERM h29* For more information, see *csh(C)*.

A user may also add variables to the environment, but must be sure that the new names do not conflict with exported shell variables such as MAIL, PS1, PS2, and IFS. Placing assignments in the *.profile* file is a useful way to change the environment automatically before a session begins. C-shell users can place assignments in their *.cshrc* files.

Note that the environment is made available to all programs as a string of arrays. Each string has the format:

name=value

where the *name* is the name of an exported variable and the *value* is the variable's current value. For programs started with a *exec(S)* call, the environment is available through the external pointer *environ*. For other programs, individual variables in environment are available through *getenv(S)* calls.

Name

fixperm - Correct or initialize file permissions and ownership.

Syntax

fixperm [-cflnsvwDS [-d *package*]] specfile

Description

For each line in the specification file *specfile*, *fixperm* makes the listed pathname conform to a specification. *fixperm* is typically used to configure a XENIX system upon installation. Non-superusers can only use *fixperm* with the -n, -f, -D or -l flags. To use any other flags, you must be superuser.

The specification file has the following format: Each non-blank line consists of either a comment or an item specification. A comment is any text from a pound sign “#” up to the end of the line. There is one item specification per line. User and group id numbers must be specified at the top of the specification file for each user and group mentioned in the file.

An item specification consists of a package specifier, a permission specification, owner and group specifications, the number of links on the file, the file name, and an optional volume number.

The package specifier is an arbitrary string which is the name of a package within a distribution set. A package is a set of files.

After the package specifier is a permission specification. The permission specification consists of a file type, followed by a numeric permission specification. The item specification is one of the following characters:

- x Executable.
- a Archive.
- e Empty file (create if -c option given).
- b Block device.
- c Character device.
- d Directory.
- f Text file.

p Named pipe.

The numeric permission conforms to the scheme described in *chmod*(C). The owner and group permissions are in the third column separated by a slash: e.g.,: "bin/bin". The fourth column indicates the number of links. If there are links to the file, the next line contains the linked filename with no other information. The fifth column is a pathname. The pathname must be relative, i.e., not preceded by a slash "/". The sixth column is only used for special files, giving the major and minor device numbers, or volume numbers.

Options

The following options are available from the command line:

- c Create empty files and missing directories.
- d *package*
Process input lines beginning with given package specifier string (see above). For instance, -dBASE processes only items specified as belonging to the Basic utilities set. The default action is to process all lines.
- u *package*
Like -u, but processes items that are not part of the given package.
- f List files only on standard output. Does not modify target files.
- i Check only if the selected packages are installed. Return values are:

0:	package completely installed
4:	package not installed
5:	package partially installed
- l List files and directories on standard output. Does not modify target files.
- n Report errors only. Does not modify target files.
- D
List directories only on standard output. Does not modify target files.
- v Verbose, in particular, issues a complaint if executable files are word swapped, not fixed stack, not separate I and D, or not stripped.

- s Modify special device files in addition to the rest of the permlist.
- w Lists where (what volume) the specified files or directories are located.
- S Issues a complaint if files are not in x.out format.

The following two lines make a distribution and invoke *tar*(C) to archive only the files in base.perms on /dev/sample:

```
/etc/fixperm -f /etc/base.perms > list  
tar cfF /dev/sample list
```

This example reports *BASE* package errors:

```
/etc/fixperm -nd BASE
```

Notes

Usually *fixperm* is only run by a shell script at installation.

custom (C)

Name

getty – Sets terminal type, modes, speed, and line discipline.

Syntax

```
/etc/getty [ -h ] [ -t timeout ] line [ speed [ type [ linedisc ] ] ]  
/etc/getty -c file
```

Description

getty is a program that is invoked by *init*(M). It is the second process in the series, (*init-getty-login-shell*), that ultimately connects a user with the XENIX system. Initially *getty* displays the login message field for the entry it is using from */etc/gettydefs*. *getty* reads the user's login name and invokes the *login*(M) command with the user's name as argument. While reading the name, *getty* attempts to adapt the system to the speed and type of terminal being used.

Line is the name of a tty line in */etc/ttys* to which *getty* is to attach itself. *getty* uses this string as the name of a file in the */dev* directory to open for reading and writing. Unless *getty* is invoked with the *-h* flag, *getty* will force a hangup on the line by setting the speed to zero before setting the speed to the default or specified speed. The *-t* flag, plus *timeout* in seconds, specifies that *getty* should exit if the open on the line succeeds and no one enters anything in the specified number of seconds. The optional second argument, *speed*, is a label to a speed and tty definition in the file */etc/gettydefs*. This definition tells *getty* what speed to initially run, what the login message should look like, what the initial tty settings are, and what speed to try next should the user indicate that the speed is inappropriate (by entering a BREAK character). The default *speed* is 300 baud. The optional third argument, *type*, is a character string describing to *getty* what type of terminal is connected to the line in question. *getty* understands the type *none*—any CRT or normal terminal unknown to the system. This is the default.

For terminal type to have any meaning, the virtual terminal handlers must be compiled into the operating system. They are available, but not compiled in the default condition. The optional fourth argument, *linedisc*, is a character string describing which line discipline to use in communicating with the terminal. Again the hooks for line disciplines are available in the operating system but there is only one presently available, the default line discipline, *LDISC0*.

When given no optional arguments, *getty* sets the *speed* of the interface to 300 baud, specifies that raw mode will be used (awaken on every character), that echo will be suppressed, either parity

allowed, that new-line characters will be converted to carriage return-line feed, and that tab expansion is performed on the standard output. It displays the login message before reading the user's name a character at a time. If a null character (or framing error) is received, it is assumed to be the result of the user pushing the BREAK key. This will cause *getty* to attempt the next *speed* in the series. The series that *getty* tries is determined by what it finds in */etc/gettydefs*.

The user's name is terminated by a new-line or carriage-return character. The latter results in the system being set to treat carriage returns appropriately (see *ioctl(S)*).

The user's name is scanned to see if it contains any lower-case alphabetic characters. *getty* suggests that the user use all lower-case characters. If the user uses upper case characters, the system is told to map any future upper-case characters into the corresponding lower-case characters.

Finally, the *login-program* from */etc/gettydefs* is called with the user's name as an argument. Additional arguments may be entered after the login name. These are passed to the *login-program*. The default *login-program*, */etc/login*, places them in the environment (see *login(M)*).

A check option is provided. When *getty* is invoked with the *-c* option and *file*, it scans the file as if it were scanning */etc/gettydefs* and prints out the results to the standard output. If there are any unrecognized modes or improperly constructed entries, it reports these. If the entries are correct, it displays the values of the various flags. See *ioctl(S)* to interpret the values. Note that some values are added to the flags automatically.

Files

/etc/gettydefs
/etc/ttys

See Also

init(M), *login(M)*, *ioctl(S)*, *gettydefs(F)*, *ttys(M)*

Name

group – Format of the group file.

Description

group contains the following information for each group:

- Group name
- Encrypted password (optional)
- Numerical group ID
- Comma-separated list of all users allowed in the group

This is an ASCII file. The fields are separated by colons; each group is separated from the next by a newline. If the password field is null, no password is demanded.

This file resides in directory */etc*. Because of the encrypted passwords, it can and does have general read permission and can be used, for example, to map numerical group IDs to names.

Files

/etc/group

See Also

newgrp(C), passwd(C), passwd(M)

Name

init, *inir* – Process control initialization.

Syntax

/etc/init
/etc/inir

Description

The *init* program is invoked as the last step of the boot procedure and as the first step in enabling terminals for user logins. *init* is one of three programs (*init*, *getty*(M), and *login*(M)) used to initialize a system for execution.

init creates a process for each terminal on which a user may log in. It begins by opening the console device, */dev/console*, for reading and writing. It then invokes a shell which prompts for a password to start the system in maintenance mode. At this point, the user can choose whether to *boot* (HW) by responding to the prompt with the password of Ctrl-D, or to *autoboot* (M). by not pressing any key, thereby allowing the system to timeout. In either event, the filesystem may be clean or dirty. So there are four possible cases, as outlined below:

The user may *autoboot* and the filesystem may be dirty. In this case, *inir* - a checks the */etc/default/boot* file for instructions. (See *autoboot* (M) for more information.)

The user may *autoboot* and the filesystem may be clean. In this case, *init* - a checks the */etc/default/boot* file for instructions and then reads commands from the */etc/rc* file. This is followed by the "multi-user/rc" and the "getty/login" procedures as documented later in this section.

The user may *boot* and the filesystem may be dirty. In this case, *inir* prompts the user, asking whether to do an *fsck* (C) (See *fsck* (C) for more information.)

The user may *boot* and the filesystem may be clean. In this case, *init* reads commands from the */etc/rc* file. This is followed by the "multi-user/rc" and the "getty/login" procedures as documented below.

"multi-user/rc" procedure: Once the filesystem is clean, the shell terminates, and *init* performs several steps to begin normal operation. It invokes a shell and reads the commands in the */etc/rc* file. This command file performs housekeeping tasks such as removing temporary files, mounting file systems, and starting daemons. Then

it reads the file */etc/ttys* and forks several times to create a process for each terminal device in the file. Each line in the */etc/ttys* lists the state of the line (0 for closed, 1 for open), the line mode, and the serial line (see *ttys(M)*). Each process opens the appropriate serial line for reading and writing, assigning the file descriptors 0, 1, and 2 to the line and establishing it as the standard input, output, and error files. If the serial line is connected to a modem, the process delays opening the line until someone has dialed up and a carrier has been established on the line.

"getty/login" procedure: Once *init* has opened a line, it executes the *getty* program, passing the line mode as an argument. The *getty* program reads the user's name and invokes *login(M)* to complete the login process (see *getty(M)* for details). *init* waits until the user logs out by typing ASCII end-of-file (Ctrl-D) or by hanging up. It responds by waking up and removing the former user's login entry from the file *utmp*, which records current users, and makes a new entry in the file *wtmp*, which is a history of logins and logouts. Then the corresponding line is reopened and *getty* is reinvoked.

init has special responses to the hangup, interrupt, and quit signals. The hangup signal SIGHUP causes *init* to change the system from normal operation to maintenance mode. The interrupt signal SIGINT causes *init* to read the *ttys* file again to open any new lines and close lines that have been removed. The quit signal SIGQUIT causes *init* to disallow any further logins. In general, these signals have a significant effect on the system and should not be used by a inexperienced user. Instead, similar functions can be safely performed with the *enable(C)*, *disable(C)*, and *shutdown(C)* commands.

Files

- /dev/tty**
- /etc/utmp*
- /usr/adm/wtmp*
- /etc/default/boot*
- /etc/ttys*
- /etc/rc*
- /etc/gettydefs*

See Also

autoboot(M), *disable(C)*, *enable(C)*, *login(M)*, *kill(C)*, *sh(C)*, *shutdown(C)*, *ttys(M)*, *getty(M)*, *gettydefs(F)*

Diagnostics

If seven or more *getty* processes are started on the same line in five minutes or less, *init* writes an error message to */dev/console* and

INIT (M)

INIT (M)

refuses to start another *getty* on that line for at least 30 minutes. If desired, *init* will try again immediately if a SIGINT is sent.

Name

install – Installation shell script.

Syntax

/etc/install [device]

Description

/etc/install is the *sh*(C) script used to install XENIX distribution (or application program) floppies. It performs the following tasks:

- Prompts for insertion of floppies.
- Extracts files using the *tar*(C) utility.
- Executes **/once/init.*** programs on each floppy after they have been extracted.
- Removes any **/once/init.*** programs when the installation is finished.

The optional argument to the command specifies the device used. The default device is **/dev/install** and is normally linked to **/dev/rfd0**.

Files

/etc/install

/once/init.*

Name

ld – Invokes the link editor.

Syntax

ld [*options*] *filename*...

Description

ld is the XENIX link editor. It creates an executable program by combining one or more object files and copying the executable result to the file **a.out**. The *filename* must name an object or library file. These names must have the “.o” (for object) or “.a” (for archive library) extensions. If more than one name is given, the names must be separated by one or more spaces. If errors occur while linking, **ld** displays an error message; the resulting **a.out** file is unexecutable.

ld concatenates the contents of the given object files in the order given in the command line. Library files in the command line are examined only if there are unresolved external references encountered from previous object files. Library files must be in *ranlib*(CP) format, that is, the first member must be named `__SYMDEF`, which is a dictionary for the library. The library is searched iteratively to satisfy as many references as possible and only those routines that define unresolved external references are concatenated. Object and library files are processed at the point they are encountered in the argument list, so the order of files in the command line is important. In general, all object files should be given before library files. **ld** sets the entry point of the resulting program to the beginning of the first routine.

There are the following options:

-Fnum

Sets the size of the program stack to *num* bytes. Default stack size if not given, is either variable stack or fixed stack of 2 Kbytes. See the *machine*(M) manual page for the default stack type for your system.

-i Creates separate instruction and data spaces for small model programs. When the output file is executed, the program text and data areas are allocated separate physical segments. The text portion will be read-only and shared by all users executing the file.**-Ms**

Creates a small model program and checks for errors, such as fixup overflow. This option is reserved for object files compiled

or assembled using the small model configuration. This is the default model if no **-M** option is given.

-Mm

Creates middle model program and checks for errors. This option is reserved for object files compiled or assembled using the middle model configuration. This option implies **-i**.

-MI

Creates a large model program and checks for errors. The option is reserved for object files compiled using the large model configuration. This option implies **-i**.

-o name

Sets the executable program filename to *name* instead of **a.out**.

ld should be invoked using the *cc*(CP) instead of invoking it directly. *Cc* invokes *ld* as the last step of compilation, providing all the necessary C-language support routines. Invoking *ld* directly is not recommended since failure to give command line arguments in the correct order can result in errors.

Files

/bin/ld

See Also

ar(CP), cc(CP), ld(CP), masm(CP), ranlib(CP)

Notes

The user must make sure that the most recent library versions have been processed with *ranlib*(CP) before linking. If this is not done, *ld* cannot create executable programs using these libraries.

Name

`login` - Gives access to the system.

Description

The *login* command is used at the beginning of each terminal session and allows you to identify yourself to the system. It cannot be invoked except when a connection is first established, or after the previous user has logged out by sending an end-of-file (`Ctrl-D`) to his initial shell.

login prompts for your user name, and if appropriate, your password. Echoing is turned off (where possible) while entering your password, so it will not appear on the written record of the session.

At some installations, an option may be invoked that will require you to enter a second "external" password. This will occur only for dial-up connections, and you will be prompted by the message "External security:". Both passwords are required for a successful login.

If password aging has been invoked by the super-user on your behalf, your password may have expired. In this case, you will be shunted into *passwd*(C) to change it, after which you may attempt to log in again.

If you do not complete the login successfully within a certain period of time (e.g., one minute), you are likely to be returned to the "login:" prompt or silently disconnected from a dial-up line.

After a successful login, accounting files (*/etc/utmp* and */etc/wtmp*) are updated, you are told if you have any mail, and the start-up profile files (i.e., */etc/profile* and *\$HOME/.profile*), if any, are executed (see *profile*(M)). *login* checks */etc/default/login* checks *ULIMIT* (maximum file size in 512 byte blocks, default is 4096), checks and for environment variables, such as *TZ*(time zone), *HZ*(hertz) *ALTSHELL* (allows other than *sh* shell types). *login* initializes the user and group IDs and the working directory, then executes a command interpreter (usually *sh*(C)) according to specifications found in the */etc/passwd* file. Argument 0 of the command interpreter is a dash (-) followed by the last component of the interpreter's pathname. The *environment* (see *environ*(M)) is initialized to:

`HOME=` your-login-directory

`PATH=`:/bin:/usr/bin

Initially, *umask* is set to octal 022 by *login*.

Files

/etc/utmp	Information on current logins
/etc/wtmp	History of logins since last multiuser
/usr/spool/mail/ <i>your-name</i>	Mailbox for user <i>your-name</i>
/etc/motd	Message of the day
/etc/default/login	Default values for environment variables
/etc/passwd	Password file
/etc/profile	System profile
\$HOME/.profile	Personal profile

See Also

environ(M), getty(M), machine(M), mail(C), newgrp(C),
passwd(C), passwd(M), profile(M), su(C), sh(C), ulimit(S),
umask(C), who(C).

Diagnostics

Login incorrect

The user name or the password is incorrect.

No shell, cannot open password file, no directory:

Your account has not been properly set up.

Your password has expired. Choose a new one.

Password aging is implemented and yours has expired.

Notes

Under System V, only the super-user may execute *login* from a shell. Hence non-super-users must log out in order to log in as another user.

Furthermore, there has been a change in *login*'s functionality. Pre-system III *login*, if invoked from the command line while someone is logged on already, logs the current user out and logs in the new user. The current *login* nests, i.e., the current user is not

logged out. Thus, it is somewhat like su, except that the new user's .login or .profile is run. Permissions and environment are those of the new user. When the new user logs out, the previous user is still running. This practice is not recommended, as nested logins can impair system performance.

When setting **ULIMIT** in the **/etc/default/login** file on filesystems with 1024 byte blocks (see **machine(M)**), be sure to specify even numbers, as the **ULIMIT** variable accepts a number of 512 byte blocks. The default is 4096 blocks, or 2 megabytes. Use this variable to increase the maximum allowable file size.

Name

makekey – Generates an encryption key.

Syntax

/usr/lib/makekey

Description

makekey improves the usefulness of encryption schemes by increasing the amount of time required to search the key space. It reads 10 bytes from its standard input, and writes 13 bytes on its standard output. The output depends on the input in a way that is intended to be difficult to compute (i.e., to require a substantial fraction of a second).

The first 8 input bytes (the *input key*) can be arbitrary ASCII characters. The last 2 input bytes (the *salt*) are best chosen from the set of digits, dot (.), slash (/), and uppercase and lowercase letters. The *salt* characters are repeated as the first 2 characters of the output. The remaining 11 output characters are chosen from the same set as the *salt* and constitute the *output key*.

The transformation performed is essentially the following: the *salt* is used to select one of 4,096 cryptographic machines all based on the National Bureau of Standards DES algorithm, but broken in 4,096 different ways. Using the *input key* as the key, a constant string is fed into the machine and recirculated. The 64 bits that come out are distributed into the 66 *output key* bits in the result.

See Also

passwd(M)

Name

mapkey, mapscrn, mapstr – Configure console screen mapping.

Syntax

```
mapkey [ -d ][ datafile ]  
mapscrn [ -d ][ datafile ]  
mapstr [ -d ][ datafile ]
```

Description

mapscrn configures the output mapping of the console screen on which it is invoked. *mapkey* and *mapstr* configure the mapping of the keyboard and string keys (eg. function keys) of the console (and multiscreens if present). *mapkey* can only be run by the super-user.

mapstr functions on a per screen basis. Mapping strings on one screen does not affect any other screen.

If a file name is given on the argument line the respective mapping table is configured from the contents of the input file. If no file is given, the default files in */usr/lib/keyboard* and */usr/lib/console* is used. The *-d* option causes the mapping table to be read from the kernel instead of written and an ASCII version to be displayed on the standard output. The format of the output is suitable for input files to *mapscrn*, *mapkey*, *mapstr*. Non-super-users can run *mapkey* and *mapstr* when the *-d* option is given.

Files

/usr/lib/keyboard/keys

/usr/lib/keyboard/strings

/usr/lib/console/screens.gr

/usr/lib/console/screens.uk

/usr/lib/console/screens.usa

Notes

There is no way to specify that these utilities read their configuration tables from standard input.

MAPKEY (M)

MAPKEY (M)

See Also

console(M), keyboard(M)

Name

mem, kmem – Memory image file.

Description

The **mem** file provides access to the computer's physical memory. All byte addresses in the file are interpreted as memory addresses. Thus, memory locations can be examined in the same way as individual bytes in a file. Note that accessing a nonexistent location causes an error.

The **kmem** file is the same as **mem** except that it corresponds to kernel virtual memory rather than physical memory.

In rare cases, the **mem** and **kmem** files may be used to write to memory and memory-mapped devices. Such patching is not intended for the naive user and may lead to a system crash if not conducted properly. Patching device registers is likely to lead to unexpected results if the device has read-only or write-only bits.

Files

/dev/mem

/dev/kmem

Name

messages – Description of system console messages.

Description

This section describes the various system messages which may appear on the system console. The messages are categorized as follows:

Fatal

Recovery is impossible.

System inconsistency

A contradictory situation exists in the kernel.

Abnormal

A probably legitimate but extreme situation exists.

Hardware

Indicates a hardware problem.

Fatal system messages begin with “panic:” and indicate hardware problems or kernel inconsistencies that are too severe for continued operation. After displaying a fatal message, the system will stop. Rebooting is required.

System inconsistency messages indicate problems usually traceable to hardware malfunction, such as memory failure. These messages rarely occur since associated hardware problems are generally detected before such an inconsistency can occur.

Abnormal messages represent kernel operation problems, such as the overflow of critical tables. It takes extreme situations to bring these problems about, so they should never occur in normal system use.

Hardware messages normally specify the device, *dev*, that caused the error. Each message gives a device specification of the form *nn/mm* where *nn* is the major number of the device, and *mm* is its minor number. The command pipeline

```
ls -l /dev | grep nn | grep mm
```

may be used to list the name of the device associated with the given major and minor numbers.

System Messages

**** ABNORMAL System Shutdown ****

This message appears when errors occur during system shutdown. It is usually accompanied by other system messages. *System inconsistency, fatal.*

bad block on dev nn/mm

A nonexistent disk block was found on, or is being inserted in, the structure's free list. *System inconsistency.*

bad count on dev nn/mm

A structural inconsistency in the superblock of a file system. The system attempts a repair, but this message will probably be followed by more complaints about this file system. *System inconsistency.*

Bad free count on dev nn/mm

A structural inconsistency in the superblock of a file system. The system attempts a repair, but this message will probably be followed by more complaints about this file system. *System inconsistency.*

error on dev name (nn/mm)

This is the way that most device driver diagnostic messages start. The message will indicate the specific driver and complaint. The *name* is a word identifying the device.

iaddress > 2²⁴

This indicates an attempted reference to an illegal block number, one so large that it could only occur on a file system larger than 8 billion bytes. *Abnormal.*

Inode table overflow

Each open file requires an inode entry to be kept in memory. When this table overflows, the specific request (usually *open(S)* or *creat(S)*) is refused. Although not fatal to the system, this event may damage the operation of various spoolers, daemons, the mailer, and other important utilities. Abnormal results and missing data files are a common result. *Abnormal.*

interrupt from unknown device, vec=xxxx

The CPU received an interrupt via a supposedly unused vector. This message is followed by "panic: unknown interrupt." Typically, this event comes about when a hardware failure miscomputes the vector of a valid interrupt. *Hardware.*

no file

There are too many open files. The system has run out of entries in its "open file" table. The warnings given for the message "inode table overflow" apply here. *Abnormal.*

no space on dev *nn/mm*

This message means that the specified file system has run out of free blocks. Although not normally as serious, the warnings discussed for "inode table overflow" apply: often user programs are written casually and ignore the error code returned when they tried to write to the disk; this results in missing data and "holes" in data files. The system administrator should keep close watch on the amount of free disk space and take steps to avoid this situation. *Abnormal*.

**** Normal System Shutdown ****

This message appears when the system has been shutdown properly. It indicates that the machine may now be rebooted or powered down.

Out of inodes on dev *nn/mm*

The indicated file system has run out of free inodes. The number of inodes available on a file system is determined when the file system is created (using *mkfs(C)*). The default number is quite generous; this message should be very rare. The only recourse is to remove some worthless files from that file system, or dump the entire system to a backup device, run *mkfs(C)* with more inodes specified, and restore the files from backup. *Abnormal*.

out of text

When programs linked with the *ld -i* or *-n* switch are run, a table entry is made so that only one copy of the pure text will be in memory even if there are multiple copies of the program running. This message appears when this table is full. The system refuses to run the program which caused the overflow. Note that there is only one entry in this table for each different pure text program. Multiple copies of one program will not require multiple table entries. Each "sticky" program (see *chmod(C)*) requires a permanent entry in this table; non-sticky pure text programs require an entry only when there is at least one copy being executed. *Abnormal*.

panic: bad 287 int

Attempted execution of a real mode 287 instruction. *System inconsistency, fatal*.

panic: blkdev

An internal disk I/O request, already verified as valid, is discovered to be referring to a nonexistent disk. *System inconsistency, fatal*.

panic: devtab

An internal disk I/O request, already verified as valid, is discovered to be referring to a nonexistent disk. *System inconsistency, fatal*.

panic: iinit

The super-block of the root file system could not be read.
This message occurs only at boot time. *Hardware, fatal.*

panic: IO err in swap

A fatal I/O error occurred while reading or writing the swap area. *Hardware, fatal.*

panic: memory failure - parity error

A hardware memory failure trap has been taken. *System inconsistency, fatal.*

panic: memory management failure

An error occurred during memory management operations.
System inconsistency, fatal.

panic: no fs

A file system descriptor has disappeared from its table. *System inconsistency, fatal.*

panic: no imt

A mounted file system has disappeared from the mount table.
System inconsistency, fatal.

panic: no procs

Each user is limited in the amount of simultaneous processes he can have; an attempt to create a new process when none is available or when the user's limit is exceeded and refused. That is an occasional event and produces no console messages; this panic occurs when the kernel has certified that a free process table entry is available and can't find one when it goes to get it. *System inconsistency, fatal.*

panic: Out of swap

There is insufficient space on the swap disk to hold a task. The system refuses to create tasks when it feels there is insufficient disk space, but it is possible to create situations to fool this mechanism. *Abnormal, fatal.*

panic: general protection trap

General protection trap taken in kernel. *System inconsistency, fatal.*

panic: segment not present

An attempt has been made to access an invalid segment. It may also indicate the segment-not-present trap has been taken in the kernel. *System inconsistency, fatal.*

panic: Timeout table overflow

The timeout table is full. Timeout requests are generated by device drivers, there should usually be room for one entry per system serial line plus ten more for other usages.

panic: Trap in system

The CPU has generated an illegal instruction trap while executing kernel or device driver code. This message is preceded with an information dump describing the trap. *System inconsistency, fatal.*

panic: Invalid TSS

Internal tables have become corrupted. *System inconsistency, fatal.*

panic: unknown interrupt

The CPU received an interrupt via a supposedly unused vector. Typically, this event comes about when a hardware failure miscomputes the vector of a valid interrupt. *Hardware, fatal.*

proc on q

The system attempts to queue a process already on the process ready-to-run queue. *System inconsistency, fatal.*

Trap type

This message precedes a "panic:" message. The *type* is the trap number given by the processor. The message is followed by a dump of registers. *System inconsistency, fatal.*

Notes

Not all messages appear on all machines. Some messages are processor dependent.

Name

micnet – The Micnet default commands file.

Description

The **micnet** file lists the system commands that may be executed through the *remote* command. The file is required for each system in a Micnet network. Whenever a *remote* command is received through the network, the Micnet programs search the **micnet** file for the system command specified with the *remote* command. If found, the command is executed. Otherwise, the command is ignored and an error message is returned to the system which issued the *remote* command.

The file may contain one or more lines. If all commands may be executed, only the line

```
executeall
```

is required in the file. Otherwise, the commands must be listed individually. A line that defines an individual command has the form:

```
command=commandpath
```

Command is the command name to be specified in a *remote* command. **Commandpath** is the full pathname of the command on the specified system. The equal sign (=) separates the command and commandpath. For example, the line:

```
cat=/bin/cat
```

defines the command name *cat* (used in the *remote* command) to refer to the system command *cat* in the */bin* directory.

When *executeall* is set, commands are sought in a series of default directories. Initially, the directories are */bin* and */usr/bin*. The default directories can be explicitly defined in the file by including a line of the form:

```
execpath=PATH=directory[:directory]...
```

The first part of the line, *execpath=PATH=*, is required. Each **directory** must be a valid pathname. The colon is required to separate directories. For example, the line:

```
execpath=PATH=/bin:/usr/bin:/usr/bobf/bin
```

sets the default directories to **/bin**, **/usr/bin**, and **/usr/bobf/bin**.

Files

/etc/default/micnet

See Also

aliases(M), **netutil(C)**, **systemid(M)**, **top(M)**

Notes

The **rcp** command cannot be executed from a remote system unless the **micnet** file contains either *executeall*, or the line

rcp=/usr/bin/rcp

Name

multiscreen - Multiple screens (device files)

Syntax

alt-Fn
alt-ctrl-Fn
alt-shift-Fn

Description

With the *multiscreen* feature, a user can access up to ten different "screens," each corresponding to a separate device file. Each screen can be viewed one at a time through the **console** video display.

The number of screens on a system depends upon the amount of memory in the computer. The system displays the number of enabled screens during the boot process.

Access

To see the next consecutive screen, enter:

Ctrl-PrtSc

To move to any screen from any other screen, enter:

alt-Fn or alt-ctrl-Fn or alt-shift-Fn

where *n* is the number of one of the "F" function keys on the console keyboard. For example:

alt-F2

selects **tty02**, and all output in that device's screen buffer is displayed on the console screen.

Files

/dev/tty[02-10]	multiscreen devices (number available depends on system memory)
/dev/console	system console screen

See Also

console(HW), keyboard(HW), serial(HW), stty(C)

Notes

Any system error messages are normally output on the **console** device file (**/dev/console**). When an error message is output, the video display reverts to the **console** device file, and the message is displayed on the screen. The **console** device is the only teletype device open during the system boot sequence and when in single user, or system maintenance mode.

Limitations to the number of multiscreens available on a system does not affect the number of serial lines or devices available. See *serial(M)* for information on available serial devices.

Note that the keystrokes given here are the default for XENIX, but your keyboard may be different. If so, see *keyboard(M)* for the appropriate substitutes. Also, any key can be programmed to generate the screen switching sequences by using the mapkey utility.

NULL (M)

NULL (M)

Name

null – The null file.

Description

Data written on a null special file is discarded.

Reads from a null special file always return 0 bytes.

Files

/dev/null

Name

passwd – The password file.

Description

Passwd contains the following information for each user:

- Login name
- Encrypted password
- Numerical user ID
- Numerical group ID
- Comment
- Initial working directory
- Program to use as shell

Refer to *finger(C)* for information in the required format of the comment field for *finger(C)* to display the information. Each user is separated from the next by a newline. If the password field is null, no password is demanded; if the shell field is null, *sh(C)* is used.

This file resides in the directory */etc*. Because the passwords are encrypted, the file has general read permission and can be used, for example, to map numerical user IDs to names.

The encrypted password consists of 13 characters chosen from a 64-character alphabet (*., /, 0-9, A-Z, a-z*), except when the password is null, in which case the encrypted password is also null. Password aging is in effect for a particular user if his encrypted password in the password file is followed by a comma and a non-null string of characters from the above alphabet. (Such a string must be introduced by the super-user.) The first character of the age denotes the maximum number of weeks for which a password is valid. A user who attempts to log in after his password has expired will be forced to supply a new one. The next character denotes the minimum period in weeks which must expire before the password may be changed. The remaining characters define the week (counted from the beginning of 1970) when the password was last changed. (A null string is equivalent to zero.) The first and second characters must have numerical values in the range 0-63, where the dot (*.*) is equal to 0 and lowercase *z* is equal to 63. If the numerical value of both characters is 0, the user will be forced to change his password the next time he logs in. If the second character is greater than the first, only the super-user will be able to change the password.

PASSWD (M)

PASSWD (M)

Files

/etc/passwd

See Also

login(M), *passwd*(C), *a64l*(S), *getpwent*(S), *group*(M), *pwadmin*(C).

Name

profile – Sets up an environment at login time.

Description

The optional file, **.profile**, permits automatic execution of commands whenever a user logs in. The file is generally used to personalize a user's work environment by setting exported environment variables and terminal mode (see **environ(C)**).

When a user logs in, the user's login shell looks for **.profile** in the login directory. If found, the shell executes the commands in the file before beginning the session. The commands in the file must have the same format as if they were entered at the keyboard. Any line beginning with the number sign (#) is considered a comment and is ignored. The following is an example of a typical file:

```
# Tell me when new mail comes in
MAIL=/usr/mail/myname
# Add my /bin directory to the shell search sequence
PATH=$PATH:$HOME/bin
# Make some environment variables global
export MAIL PATH TERM
# Set file creation mask
umask 22
```

Note that the file **/etc/profile** is a system-wide profile that, if it exists, is executed for every user before the user's **.profile** is executed.

Files

```
$HOME/.profile
/etc/profile
```

Name

setclock – Sets the system real-time (time of day) clock.

setclock [*time*]

Description

The **setclock** file sets the battery-powered, real-time time of day clock to the given *time*. If *time* is not given, the current contents of the battery-powered clock are displayed. The *time* must be a combination of digits with the form:

MMddhhmmyy

where *MM* is the month, *dd* is the day, *hh* is the hour, *mm* is the minute, and *yy* is the last two digits of the year. If *yy* is not given, it is taken from the current system time. For example, the command:

082615035

sets the time of day clock to 15:03 on August 26, 1985.

Files

/etc/setclock

See Also

clock(M)

Notes

Not all computers have battery-powered real-time time of day clocks. Refer to your computer's hardware reference manual.

Name

setkey – Assigns the function keys.

Syntax

setkey *keynum string*

Description

The **setkey** command assigns the given ANSI *string* to be the output of the computer function key given by *keynum*. For example, the command:

```
setkey 1 date
```

assigns the string "date" as the output of function key 1. The *string* can contain control characters, such as a newline character, and should be quoted to protect it from processing by the shell. For example, the command:

```
setkey 2 "pwd ; lc\n"
```

assigns the command sequence "pwd ; lc" to function key 2. Notice how the newline character is embedded in the quoted string. This causes the commands to be carried out when function key 2 is pressed. Otherwise, the Enter key would have to be pressed after pressing the function key, as in the previous example.

Files

/bin/setkey

See Also

keyboard(M)

Notes

setkey works only on the *console* keyboard.

The string mapping table is where the function keys are defined. It is an array of 256 bytes (typedef *strmap_t*) where null terminated strings can be put to redefine the function keys. The first null terminated string is assigned to the first string key and the second string key and so on.

There is no limit on the length of any particular string as long as the whole table does not exceed 256 bytes, including nulls. Strings can be made null by the introduction of extra null characters.

Name

systemid – The Micnet system identification file.

Description

The **systemid** file contains the machine and site names for a system in a Micnet network. A *machine name* identifies a system and distinguishes it from other systems in the same network. A *site name* identifies the network to which a system belongs and distinguishes the network from other networks in the same chain.

The **systemid** file may contain a *site name* and up to four different *machine names*. The file has the form:

```
[site-name]  
[machine-name1]  
[machine-name2]  
[machine-name3]  
[machine-name4]
```

The file must contain at least one machine name. The other machine names are optional, serving as alternate names for the same machine. The file must contain a site name if more than one machine name is given or if the network is connected to another through a uucp link. The site name, when given, must be on the first line.

Each name can have up to eight letters and numbers but must always begin with a letter. There is never more than one name to a line. A line beginning with a pound sign (#) is considered a comment line and is ignored.

The Micnet network requires one **systemid** file on each system in a network with each file containing a unique set of machine names. If the network is connected to another network through a uucp link, each file in the network must contain the same site name.

The **systemid** file is used primarily during resolution of aliases. When aliases contain site and/or machine names, the name is compared with the names in the file and removed if there is a match. If there is no match, the alias (and associated message, file, or command) is passed on to the specified site or machine for further processing.

Name

termcap – Terminal capability data base.

Description

The file `/etc/termcap` is a data base describing terminals. This data base is used by commands such as `vi(C)`, `vsh(C)`, `Lyrix®`, `Multiplan™` and sub-routine packages such as `curses(S)`. Terminals are described in *termcap* by giving a set of capabilities and by describing how operations are performed. Padding requirements and initialization sequences are included in *termcap*.

Entries in *termcap* consist of a number of ':' separated fields. The first entry for each terminal gives the names which are known for the terminal, separated by vertical bar (|) characters. The first name is always 2 characters long for compatibility with older systems. The second name given is the most common abbreviation for the terminal and the name used by `vi (C)` and `ex(C)`. The last name given should be a long name fully identifying the terminal. Only the last name may contain blanks for readability.

Capabilities (including XENIX Extensions)

The following is a list of the capabilities that can be defined for a given terminal. In this list, (P) indicates padding may be specified, and (P*) indicates that padding may be based on the number of lines affected. The capability type and padding fields are described in detail in the following section "Types of Capabilities."

The codes beginning with uppercase letters (except for CC) indicate XENIX extensions. They are included in addition to the standard entries and are used by one or more application programs. As with the standard entries, not all modes are supported by all applications or terminals. Some of these entries refer to specific terminal output capabilities (such as GS for graphics start). Others describe character sequences sent by keys that appear on a keyboard (such as PU for PageUp key). There are also entries which are used to attribute special meanings to other keys (or combinations of keys) for use in a particular software program. Some of the XENIX extension capabilities have a similar function to standard capabilities. They are used to redefine specific keys (such as using function keys as arrow keys). The extension capabilities are included in the `/etc/termcap` file as they are required for some XENIX utilities (such as `vsh(C)`). The more commonly used extension capabilities are described in more detail in the section "XENIX Extensions."

Name	Type	Pad?	Description
ae	str	(P)	End alternate character set
al	str	(P*)	Add new blank line
am	bool		Terminal has automatic margins
as	str	(P)	Start alternate character set
bc	str		Backspace if not [^] H
bs	bool		Terminal can backspace with [^] H
bt	str	(P)	Back tab
bw	bool		Backspace wraps from column 0 to last column
CC	str		Command character in prototype if terminal settable
cd	str	(P*)	Clear to end of display
ce	str	(P)	Clear to end of line
CF	str		Cursor off
ch	str	(P)	Like cm but horizontal motion only, line stays same
CL	str		Sent by CHAR LEFT key
cl	str	(P*)	Clear screen
cm	str	(P)	Cursor motion
co	num		Number of columns in a line
CO	str		Cursor on
cr	str	(P*)	Carriage return, (default [^] M)
cs	str	(P)	Change scrolling region (vt100), like cm
cv	str	(P)	Like ch but vertical only.
CW	str		Sent by CHANGE WINDOW key
da	bool		Display may be retained above
DA	bool		Delete attribute string
db	bool		Display may be retained below
dB	num		Number of millisec of bs delay needed
dC	num		Number of millisec of cr delay needed
dc	str	(P*)	Delete character
dF	num		Number of millisec of ff delay needed
dl	str	(P*)	Delete line
dm	str		Delete mode (enter)
dN	num		Number of millisec of nl delay needed
do	str		Down one line
dT	num		Number of millisec of tab delay needed
ed	str		End delete mode
ei	str		End insert mode; give [`] ei= [`] if ic
EN	str		Sent by END key
eo	bool		Can erase overstrikes with a blank
ff	str	(P*)	Hardcopy terminal page eject (default [^] L)
G1	str		Upper-right (1st quadrant) corner character
G2	str		Upper-left (2nd quadrant) corner character

Name	Type	Pad?	Description
G3	str		Lower-left (3rd quadrant) corner character
G4	str		Lower-right (4th quadrant) corner character
GC	str		Center graphics character (similar to "+")
GD	str		Down-tick character
GE	str		Graphics mode end
GG	num		Number of chars taken by GS and GE
GH	str		Horizontal bar character
GL	str		Left-tick character
GR	str		Right-tick character
GS	str		Graphics mode start
GU	str		Up-tick character
GV	str		Vertical bar character
hc	bool		Hardcopy terminal
hd	str		Half-line down (forward 1/2 linefeed)
HM	str		Sent by HOME key (if not kh)
ho	str		Home cursor (if no cm)
hu	str		Half-line up (reverse 1/2 linefeed)
hz	str		Hazeltine; can't print ~'s
ic	str	(P)	Insert character
if	str		Name of file containing is
im	str		Insert mode (enter); give ':im=' if ic
in	bool		Insert mode distinguishes nulls on display
ip	str	(P*)	Insert pad after character inserted
is	str		Terminal initialization string
k0-k9	str		Sent by 'other' function keys 0-9
kb	str		Sent by backspace key
kd	str		Sent by terminal down arrow key
ke	str		Out of 'keypad transmit' mode
kh	str		Sent by home key
kl	str		Sent by terminal left arrow key
kn	num		Number of 'other' keys
ko	str		Termcap entries for other non-function keys
kr	str		Sent by terminal right arrow key
ks	str		Put terminal in 'keypad transmit' mode
ku	str		Sent by terminal up arrow key
l0-l9	str		Labels on 'other' function keys
LD	str		Sent by line delete key
LF	str		Sent by line feed key
li	num		Number of lines on screen or page
ll	str		Last line, first column (if no cm)
ma	str		Arrow key map, used by vi version 2 only
mi	bool		Safe to move while in insert mode
ml	str		Memory lock on above cursor
MP	str		Multiplan initialization string
MR	str		Multiplan reset string
ms	bool		Will scroll in stand-out mode
mu	str		Memory unlock (turn off memory lock)

Name	Type	Pad?	Description
nc	bool		No correctly working carriage return (DM2500,H2000)
nd	str		Non-destructive space (cursor right)
nl	str	(P*)	Newline character (default \n)
ns	bool		Terminal is a CRT but doesn't scroll
NU	str		Sent by NEXT UNLOCKED CELL key
os	bool		Terminal overstrikes
pc	str		Pad character (rather than null)
PD	str		Sent by PAGE DOWN key
pt	bool		Has hardware tabs (may need to be set with is)
PU	str		Sent by PAGE UP key
RC	str		Sent by RECALC key
RF	str		Sent by TOGGLE REFERENCE key
RT	str		Sent by RETURN key
se	str		End stand out mode
sf	str	(P)	Scroll forwards
sg	num		Number of blank chars left by so or se
so	str		Begin stand out mode
sr	str	(P)	Scroll reverse (backwards)
ta	str	(P)	Tab (other than ^I or with padding)
tc	str		Entry of similar terminal - must be last
te	str		String to end programs that use cm
ti	str		String to begin programs that use cm
uc	str		Underscore one char and move past it
ue	str		End underscore mode
ug	num		Number of blank chars left by us or ue
ul	bool		Terminal underlines even though it doesn't overstrike
up	str		Upline (cursor up)
UP	str		Sent by up-arrow key (alternate to ku)
us	str		Start underscore mode
vb	str		Visible bell (may not move cursor)
ve	str		Sequence to end open/visual mode
vs	str		Sequence to start open/visual mode
WL	str		Sent by WORD LEFT key
WR	str		Sent by WORD RIGHT key
xb	bool		Beehive (f1=escape, f2=ctrl C)
xn	bool		A newline is ignored after a wrap (Concept)
xr	bool		Return acts like ce \r \n (Delta Data)
xs	bool		Standard out not erased by writing over it (HP 264?)
xt	bool		Tabs are destructive, magic so char (Teleray 1061)

A Sample Entry

The following entry describes the Concept-100, and is among the more complex entries in the *termcap* file. (This particular concept entry is outdated, and is used as an example only.)

```
c1 |c100 |concept100:is=\EU\ef\E7\E5\E8\EI\ENH\EK\E\200\Eo&\200:\
:al=3*\E R:am:bs:cd=16*\E^C:ce=16\E^S:cl=2*\L:\
:cm=\Ea%+ %+ :co#80:dc=16\E^A:dl=3*\E B:\
:ei=\E\200:eo:im=\E^P:in:ip=16*:li#24:mi:nd=\E=:\
:se=\Ed\Ee:so=\ED\EE:ta=8\t:ul:up=\E;:vb=\Ek\EK:xn:
```

Entries may continue onto multiple lines by giving a \ as the last character of a line. Empty fields may be included for readability between the last field on a line and the first field on the next. Capabilities in *termcap* are of three types: Boolean capabilities, which indicate that the terminal has some particular feature, numeric capabilities giving the size of the terminal or the size of particular delays, and string capabilities, which give a sequence that can be used to perform particular terminal operations.

Types of Capabilities

All capabilities have two letter codes. For instance, the fact that the Concept has 'automatic margins' (i.e., an automatic return and linefeed when the end of a line is reached) is indicated by the capability **am**. The description of the Concept includes **am**. Numeric capabilities are followed by the character '#' and then the value. Thus **co**, which indicates the number of columns the terminal has, gives the value '80' for the Concept.

Finally, string valued capabilities, such as **ce** (clear to end of line sequence) are given by the two character code, an '=', and then a string ending at the next following '.'. A delay in milliseconds may appear after the '=' in such a capability, and padding characters are supplied by the editor after the remainder of the string is sent to provide this delay. The delay can be either a integer, e.g., '20', or an integer followed by an '*', i.e. '3*'. A '*' indicates that the padding required is proportional to the number of lines affected by the operation, and the amount given is the per-affected-unit padding required. When a '*' is specified, it is sometimes useful to give a delay of the form '3.5' to specify a delay per unit to tenths of milliseconds.

A number of escape sequences are provided in the string valued capabilities for easy encoding of characters there. A **\E** maps to an ESCAPE character, **\x** maps to a control-x for any appropriate x, and the sequences **\n** **\r** **\t** **\b** **\f** give a newline, return, tab, backspace and formfeed. Finally, characters may be given as three octal digits after a \, and the characters ^ and \ may be given as ^ and \\. If it is necessary to place a : in a capability, it must be escaped in octal as **\072**. If it is necessary to place a null character in a string

capability, it must be encoded as `\200`. The routines that deal with *termcap* use C strings, and strip the high bits of the output very late so that a `\200` comes out as a `\000` would.

Preparing Descriptions

We now outline how to prepare descriptions of terminals. The most effective way to prepare a terminal description is by imitating the description of a similar terminal in *termcap* and to build up a description gradually, using partial descriptions with *ex* to check that they are correct. Be aware that a very unusual terminal may expose deficiencies in the ability of the *termcap* file to describe it. To test a new terminal description, you can set the environment variable `TERMCAP` to a pathname of a file containing the description you are working on and the editor will look there rather than in */etc/termcap*. `TERMCAP` can also be set to the *termcap* entry itself to avoid reading the file when starting up the editor.

Basic capabilities

The number of columns on each line for the terminal is given by the `co` numeric capability. If the terminal is a CRT, the number of lines on the screen is given by the `li` capability. If the terminal wraps around to the beginning of the next line when it reaches the right margin, it should have the `am` capability. If the terminal can clear its screen, this is given by the `cl` string capability. If the terminal can backspace, it should have the `bs` capability, unless a backspace is accomplished by a character other than `H` in which case you should give this character as the `bc` string capability. If it overstrikes (rather than clearing a position when a character is struck over), it should have the `os` capability.

A very important point here is that the local cursor motions encoded in *termcap* are undefined at the left and top edges of a CRT terminal. The editor will never attempt to backspace around the left edge, nor will it attempt to go up locally off the top. The editor assumes that feeding off the bottom of the screen will cause the screen to scroll up, and the `am` capability tells whether the cursor sticks at the right edge of the screen. If the terminal has switch selectable automatic margins, the *termcap* file usually assumes that this is on (i.e., `am`).

These capabilities suffice to describe hardcopy and 'glass-tty' terminals. Thus the model 33 teletype is described as

```
t3 |33 |tty33:co#72:os
```

while the Lear Siegler ADM-3 is described as

```
cl |adm3|3|lsi adm3:am:bs:cl=^Z:li#24:co#80
```

Cursor addressing

Cursor addressing in the terminal is described by a **cm** string capability. This capability uses *printf*(S) like escapes (such as %x) in it. These substitute to encodings of the current line or column position, while other characters are passed through unchanged. If the **cm** string is thought of as being a function, its arguments are the line and then the column to which motion is desired, and the % encodings have the following meanings:

%d	replaced by line/column position, 0 origin
%2	like %2d - 2 digit field
%3	like %3d - 3 digit field
%.	like <i>printf</i> (S) %c
%+x	adds x to value, then %.
%>xy	if value > x adds y, no output.
%r	reverses order of line and column, no output
%i	increments line/column position (for 1 origin)
%%	gives a single %
%n	exclusive or row and column with 0140 (DM2500)
%B	BCD (16*(x/10)) + (x%10), no output.
%D	Reverse coding (x-2*(x%16)), no output. (Delta Data).

Consider the HP2645, which, to get to row 3 and column 12, needs to be sent `\E&a12c03Y` padded for 6 milliseconds. Note that the order of the rows and columns is inverted here, and that the row and column are printed as two digits. Thus its **cm** capability is '`cm=6\E&%r%2c%2Y`'. The Microterm ACT-IV needs the current row and column sent preceded by a `^T`, with the row and column simply encoded in binary, '`cm=^T%.%.` '. Terminals which use '`%.` ' need to be able to backspace the cursor (`bs` or `bc`), and to move the cursor up one line on the screen (`up` introduced below). This is necessary because it is not always safe to transmit `\t`, `\n`, `^D` and `\r`, as the system may change or discard them.

A final example is the LSI ADM-3a, which uses row and column offset by a blank character, thus '`cm=\E=%+ %+` '.

Cursor motions

If the terminal can move the cursor one position to the right, leaving the character at the current position unchanged, this sequence should be given as `nd` (non-destructive space). If it can move the cursor up a line on the screen in the same column, it should be given as `up`. If the terminal has no cursor addressing capability, but can home the cursor (to very upper left corner of screen), this can be given as `ho`; similarly, a fast way of getting to the lower left hand corner can be given as `ll`; this may involve going up with `up` from the home position, but the editor will never do this itself

(unless `ll` does) because it makes no assumption about the effect of moving up from the home position.

Area clears

If the terminal can clear from the current position to the end of the line, leaving the cursor where it is, the sequence should be given as `ce`. If the terminal can clear from the current position to the end of the display, the sequence should be given as `cd`. The editor only uses `cd` from the first column of a line.

Insert/delete line

If the terminal can open a new blank line before the line where the cursor is, the sequence should be given as `al`. Note that this is done only from the first position of a line. The cursor must then appear on the newly blank line. If the terminal can delete the line which the cursor is on, the sequence should be given as `dl`. This is done only from the first position on the line to be deleted. If the terminal can scroll the screen backwards, the sequence can be given as `sb`, but `al` can suffice. If the terminal can retain display memory above, the `da` capability should be given, and if display memory can be retained below, then `db` should be given. These let the editor know that deleting a line on the screen may bring non-blank lines up from below or that scrolling back with `sb` may bring down non-blank lines.

Insert/delete character

There are two basic kinds of intelligent terminals with respect to the insert/delete character which can be described using *termcap*. The most common insert/delete character operations affect only the characters on the current line and shift characters off the end of the line. Other terminals, such as the Concept 100 and the Perkin Elmer Owl, make a distinction between typed and untyped blanks on the screen, shifting upon an insert or delete only to an untyped blank on the screen which is either eliminated, or expanded to two untyped blanks. You can find out which kind of terminal you have by clearing the screen and entering text separated by cursor motions. Enter 'abc def', using local cursor motions (not spaces) between the 'abc' and the 'def'. Then position the cursor before the 'abc' and put the terminal in insert mode. If entering characters causes the rest of the line to shift rigidly and characters to fall off the end, your terminal does not distinguish between blanks and untyped positions. If the 'abc' shifts over to the 'def' which then move together around the end of the current line and onto the next as you insert, you have the second type of terminal, and should give the capability `in`, which stands for 'insert null'. No known terminals have an insert mode, not falling into one of these two classes.

The editor can handle both terminals that have an insert mode and terminals which send a simple sequence to open a blank position on the current line. Specify **im** as the sequence to get into insert mode, or give it an empty value if your terminal uses a sequence to insert a blank position. Specify **ei** as the sequence to leave insert mode (specify this with an empty value if you also gave **im** an empty value). Now specify **ic** as any sequence needed to be sent just before sending the character to be inserted. Most terminals with a true insert mode will not support **ic**, terminals which send a sequence to open a screen position should give it here. (Insert mode is preferable to the sequence to open a position on the screen if your terminal has both.) If post insert padding is needed, give this as a number of milliseconds in **ip** (a string option). Any other sequence which may need to be sent after an insert of a single character may also be given in **ip**.

It is occasionally necessary to move around while in insert mode to delete characters on the same line (e.g., if there is a tab after the insertion position). If your terminal allows motion while in insert mode, you can give the capability **mi** to speed up inserting in this case. Omitting **mi** will affect only speed. Some terminals (notably Datamedia's) must not have **mi** because of the way their insert mode works.

Finally, you can specify delete mode by giving **dm** and **ed** to enter and exit delete mode, and **dc** to delete a single character while in delete mode.

Highlighting, underlining, and visible bells

If your terminal has sequences to enter and exit standout mode, these can be given as **so** and **se** respectively. If there are several flavors of standout mode (such as reverse video, blinking, or underlining - half bright is not usually an acceptable 'standout' mode unless the terminal is in reverse video mode constantly), the preferred mode is reverse video by itself. It is acceptable, if the code to change into or out of standout mode leaves one, or even two blank spaces on the screen, as the TVI 912 and Teleray 1061 do. Although it may confuse some programs slightly, it cannot be helped.

Codes to begin underlining and end underlining can be given as **us**, and **ue** respectively. If the terminal has a code to underline the current character and move the cursor one space to the right, such as the Microterm Mime, the sequence can be given as **uc**. (If the underline code does not move the cursor to the right, specify the code followed by a nondestructive space.)

If the terminal has a way of flashing the screen to indicate an error quietly (a bell replacement), the sequence can be given as **vb**; it must not move the cursor. If the terminal should be placed in a different mode during open and visual modes of **ex**, the sequence

can be given as *vs* and *ve*, sent at the start and end of these modes respectively. These can be used to change from a underline to a block cursor and back.

If the terminal needs to be in a special mode when running a program that addresses the cursor, the codes to enter and exit this mode can be given as *ti* and *te*. This arises, for example, from terminals like the Concept with more than one page of memory. If the terminal has only memory relative cursor addressing and not screen relative cursor addressing, a one screen-sized window must be fixed into the terminal for cursor addressing to work properly.

If your terminal correctly generates underlined characters (with no special codes needed), even though it does not overstrike, you should give the capability *ul*. If overstrikes are erasable with a blank, this should be indicated by specifying *eo*.

Keypad

If the terminal has a keypad that transmits codes when the keys are pressed, this information can be given. Note that it is not possible to handle terminals where the keypad only works in local (this applies, for example, to the unshifted HP 2621 keys). If the keypad can be set to transmit or not to transmit, enter these codes as *ks* and *ke*. Otherwise, the keypad is assumed to always transmit. The codes sent by the left arrow, right arrow, up arrow, down arrow, and home keys can be given as *kl*, *kr*, *ku*, *kd*, and *kh*. If there are function keys such as *f0*, *f1*, ..., *f9*, the codes they send can be given as *k0*, *k1*, ..., *k9*. If these keys have labels other than the default *f0* through *f9*, the labels can be given as *l0*, *l1*, ..., *l9*. If there are other keys that transmit the same code as the terminal expects for the corresponding function, such as clear screen, the *termcap* 2 letter codes can be given in the *ko* capability, for example, *:ko=cl,ll,sf,sb:*, which says that the terminal has clear, home down, scroll down, and scroll up keys that transmit the same thing as the *cl*, *ll*, *sf*, and *sb* entries.

The *ma* entry is also used to indicate arrow keys on terminals which have single character arrow keys. It is obsolete, but still in use in version 2 of *vi*, which must be run on some minicomputers due to memory limitations. This field is redundant with *kl*, *kr*, *ku*, *kd*, and *kh*. It consists of groups of two characters. In each group, the first character is what an arrow key sends, the second character is the corresponding *vi* command. These commands are *h* for *kl*, *j* for *kd*, *k* for *ku*, *l* for *kr*, and *H* for *kh*. For example, the Mime would be *:ma=Kj^Zk^Xl:* indicating arrow keys left (^H), down (^K), up (^Z), and right (^X). (There is no home key on the Mime.)

Miscellaneous

If the terminal requires other than a null (zero) character as a pad, this can be given as **pc**.

If tabs on the terminal require padding, or if the terminal uses a character other than **I** to tab, the sequence can be given as **ta**.

Terminals that do not allow **~** characters to be displayed (such as Hazeltines), should indicate **hz**. Datamedia terminals that echo carriage-return-linefeed for carriage return, and then ignore a following linefeed, should indicate **nc**. Early Concept terminals, that ignore a linefeed immediately after an **am** wrap, should indicate **xn**. If an erase-eol is required to get rid of standout (instead of merely writing on top of it), **xs** should be given. Teleray terminals, where tabs turn all characters moved over to blanks, should indicate **xt**. Other specific terminal problems may be corrected by adding more capabilities of the form **xx**.

If the leading character for commands to the terminal (normally the escape character) can be set by the software, specify the command character(s) with the capability **CC**.

Other capabilities include **is**, an initialization string for the terminal, and **if**, the name of a file containing long initialization strings. These strings are expected to properly clear and then set the tabs on the terminal, if the terminal has settable tabs. If both are given, **is** is displayed before **if**. This is useful where **if** is **/usr/lib/tabset/std**, but **is** clears the tabs first.

Similar Terminals

If there are two very similar terminals, one can be defined as being just like the other with certain exceptions. The string capability, **tc**, can be given with the name of the similar terminal. This capability must be *last* and the combined length of the two entries must not exceed 1024. Since *termlib* routines search the entry from left to right, and since the **tc** capability is replaced by the corresponding entry, the capabilities given at the left override the ones in the similar terminal. A capability can be cancelled with **xx@** where **xx** is the capability. For example:

```
hn |2621nl:ks@:ke@:tc=2621:
```

This defines a 2621nl that does not have the **ks** or **ke** capabilities, and does not turn on the function key labels when in visual mode. This is useful for different modes for a terminal, or for different user preferences.

XENIX Extensions

Capabilities This table lists the (previously listed) XENIX extensions to the termcap capabilities. It shows which codes generate information input from the keyboard to the program reading the keyboard and which codes generate information output from the program to the screen.

Name	Input/Output	Description
CF	str	Cursor off
CL	str	Sent by CHAR LEFT key
CO	str	Cursor on
CW	str	Sent by CHANGE WINDOW key
DA	bool	Delete attribute string
EN	str	Sent by END key
G1	str	Upper-right (1st quadrant) corner character
G2	str	Upper-left (2nd quadrant) corner character
G3	str	Lower-left (3rd quadrant) corner character
G4	str	Lower-right (4th quadrant) corner character
GC	str	Center graphics character (similar to +)
GD	str	Down-tick character
GE	str	Graphics mode end
GG	num	Number of chars taken by GS and GE
GH	str	Horizontal bar character
GL	str	Left-tick character
GR	str	Right-tick character
GS	str	Graphics mode start
GU	str	Up-tick character
GV	str	Vertical bar character
HM	str	Sent by HOME key (if not kh)
MP	str	Multiplan initialization string
MR	str	Multiplan reset string
NU	str	Sent by NEXT UNLOCKED CELL key
PD	str	Sent by PAGE DOWN key
PU	str	Sent by PAGE UP key
RC	str	Sent by RECALC key
RF	str	Sent by TOGGLE REFERENCE key
RT	str	Sent by RETURN key
UP	str	Sent by up-arrow key (alternate to ku)
WL	str	Sent by WORD LEFT key
WR	str	Sent by WORD RIGHT key

Cursor motion Some application programs make use of special editing codes. CR and CL move the cursor one character right and left respectively. WR and WL move the cursor one word right and left respectively. CW changes windows, when they are used in the program.

Some application programs turn off the cursor. This is accomplished using CF for cursor off and CO to turn it back on.

Graphic mode. If the terminal has graphics capabilities, this mode can be turned on and off with the GS and GE codes. Some terminals generate graphics characters from all keys when in graphics mode (such as the Visual 50). The other G codes specify particular graphics characters accessed by escape sequences. These characters are available on some terminals as alternate graphics character sets (not as a bit-map graphic mode). The vt100 has access to this kind of alternate graphics character set, but not to a bit-map graphic mode.

Credit

This utility was developed at the University of California at Berkeley and is used with permission.

Notes

ex(C) allows only 256 characters for string capabilities, and the routines in *termcap(S)* do not check for overflow of this buffer. The total length of a single entry (excluding only escaped newlines) may not exceed 1024.

The *ma*, *vs*, and *ve* entries are specific to the *vi(C)* program.

Not all programs support all entries. There are entries that are not supported by any program.

XENIX termcap extensions are explained in detail in the software application documentation.

Refer to the *console(M)* manual page, for a description of the character sequences used by the console device on your specific XENIX System.

Name

terminals – List of supported terminals.

Description

The following list, derived from the file `/etc/termcap`, shows the terminal name (suitable for use as a TERM shell variable), and a short description of the terminal. The advice in `termcap(M)` will assist users in creating termcap entries for terminals not currently supported.

Name	Terminal
2621	hp 2621
2621wl	hp 2621 with labels
3045	Datamedia 3045a
4025	Tektronix 4024/4025/4027
4025-17	Tek 4025 17 line window
4025-17ws	Tek 4025 17 line window in workspace
4025ex	Tek 4025
5425	AT&T teletype
5425-w	AT&T teletype with 132 columns
8001	ISC8001

tset(C), environ(M), termcap(M)

Name

termio – General terminal interface.

Description

All asynchronous communications ports use the same general interface, no matter what hardware is involved. The remainder of this section discusses the common features of this interface.

When a terminal file is opened, it normally causes the process to wait until a connection is established. In practice, users' programs seldom open these files; they are opened by *getty*(M) and become a user's standard input, output, and error files. The very first terminal file opened by the process group leader of a terminal file not already associated with a process group becomes the "control terminal" for that process group. The control terminal plays a special role in handling quit and interrupt signals, as discussed below. The control terminal is inherited by a child process during a *fork*(S). A process can break this association by changing its process group using *setpgrp*(S).

A terminal associated with one of these files ordinarily operates in full-duplex mode. Characters can be entered at any time, even while output is occurring, and are only lost when the system's character input buffers become completely full, which is rare, or when the user has accumulated the maximum allowed number of input characters that have not yet been read by some program. Currently, this limit is 256 characters. When the input limit is reached, all the saved characters are thrown away without notice.

Normally, terminal input is processed in units of lines. A line is delimited by a newline (ASCII LF) character, an end-of-file (ASCII EOT) character, or an end-of-line character. This means that a program attempting to read will be suspended until an entire line has been entered. Also, no matter how many characters are requested in the read call, one line will be returned at most. It is not, however, necessary to read a whole line at once; any number of characters may be requested in a read, even one, without losing information.

Erase and kill processing is normally done during input. By default, a Ctrl-H or BACKSPACE erases the last character typed, except that it will not erase beyond the beginning of the line. By default, a Ctrl-U kills (deletes) the entire input line, and optionally outputs a newline character. Both these characters operate on a key-stroke basis, independent of any backspacing or tabbing that may have been done. Both the erase and kill characters may be entered literally by preceding them with the escape character (\). In this case, the escape character is not read. The erase and kill characters may be changed (see *stty*(C)).

Certain characters have special functions on input. These functions and their default character values are summarized as follows:

INTR	(Rubout or ASCII DEL) Generates an <i>interrupt</i> signal which is sent to all processes with the associated control terminal. Normally, each such process is forced to terminate, but arrangements may be made either to ignore the signal or to receive a trap to an agreed-upon location; see <i>signal(S)</i> .
QUIT	(Ctrl-\ or ASCII FS) Generates a <i>quit</i> signal. Its treatment is identical to the interrupt signal except that, unless a receiving process has made other arrangements, it will not only be terminated, but a core image file (called <i>core</i>) will be created in the current working directory.
ERASE	(Ctrl-H) Erases the preceding character. It will not erase beyond the start of a line, as delimited by a NL, EOF, or EOL character.
KILL	(Ctrl-U) Deletes the entire line, as delimited by a NL, EOF, or EOL character.
EOF	(Ctrl-D or ASCII EOT) May be used to generate an end-of-file from a terminal. When received, all the characters waiting to be read are immediately passed to the program, without waiting for a newline, and the EOF is discarded. Thus, if there are no characters waiting, which is to say the EOF occurred at the beginning of a line, zero characters will be passed back, which is the standard end-of-file indication.
NL	(ASCII LF) Is the normal line delimiter. It cannot be changed or escaped.
EOL	(ASCII NUL) Is an additional line delimiter, like NL. It is not normally used.
STOP	(Ctrl-S or ASCII DC3) Temporarily suspends output. It is useful with CRT terminals to prevent output from disappearing before it can be read. While output is suspended, STOP characters are ignored and not read.
START	(Ctrl-Q or ASCII DC1) Resumes output which has been suspended by a STOP character. While output is not suspended, START characters are ignored and not read. The START/STOP characters cannot be changed or escaped.

The character values for INTR, QUIT, ERASE, KILL, EOF, and EOL may be changed to suit individual tastes. The ERASE, KILL, and EOF characters may be escaped by a preceding backslash (\) character, in which case no special function is carried out.

When the carrier signal from the dataset drops, a "hangup" signal is sent to all processes that have this terminal as the control terminal. Unless other arrangements have been made, this signal causes the processes to terminate. If the hangup signal is ignored, any subsequent read returns with an end-of-file indication. Thus, programs that read a terminal and test for an end-of-file can terminate appropriately when hung up on.

When one or more characters are written, they are transmitted to the terminal as soon as the previously typed characters have been entered. Input characters are echoed by putting them in the output queue as they arrive. If a process produces characters more rapidly than they can be typed, it will be suspended when its output queue exceeds a given limit. When the queue has drained down to the given threshold, the program is resumed.

Several *ioctl*(S) system calls apply to terminal files. The primary calls use the following structure, defined in the file `<termio.h>`:

```
#define NCC      8
struct termio {
    unsigned short c_iflag;    /* input modes */
    unsigned short c_oflag;    /* output modes */
    unsigned short c_cflag;    /* control modes */
    unsigned short c_lflag;    /* local modes */
    char           c_line;     /* line discipline */
    unsigned char  c_cc[NCC]; /* control chars */
};
```

The special control characters are defined by the array `c_cc`. The relative positions and initial values for each function are as follows:

```
0  VINTR  DEL
1  VQUIT  FS
2  VERASE Ctrl-H
3  VKILL   Ctrl-U
4  VEOF/VMINEOT
5  VEOL/VTIMENUL
6  Reserved
7  Reserved
```

The `c_iflag` field describes the basic terminal input control:

```
IGNBRK    0000001  Ignores break condition
BRKINT     0000002  Signals interrupt on break
IGNPAR     0000004  Ignores characters with parity errors
PARMRK     0000010  Marks parity errors
```

INPCK	0000020	Enables input parity check
ISTRIP	0000040	Strips character
INLCR	0000100	Maps NL to CR on input
IGNCR	0000200	Ignores CR
ICRNL	0000400	Maps CR to NL on input
IUCLC	0001000	Maps uppercase to lowercase on input
IXON	0002000	Enables start/stop output control
IXANY	0004000	Enables any character to restart output
IXOFF	0010000	Enables start/stop input control

If IGNBRK is set, the break condition (a character framing error with data all zeros) is ignored, that is, not put on the input queue and therefore not read by any process. Otherwise, if BRKINT is set the break condition will generate an interrupt signal and flush both the input and output queues. If IGNPAR is set, characters with other framing and parity errors are ignored.

If PARMRK is set, a character with a framing or parity error which is not ignored is read as the 3-character sequence: 0377, 0, X, where X is the data of the character received in error. To avoid ambiguity in this case, if ISTRIP is not set, a valid character of 0377 is read as 0377, 0377. If PARMRK is not set, a framing or parity error which is not ignored is read as the character NUL (0).

If INPCK is set, input parity checking is enabled. If INPCK is not set, input parity checking is disabled. This allows output parity generation without input parity errors.

If ISTRIP is set, valid input characters are first stripped to 7-bits, otherwise all 8-bits are processed.

If INLCR is set, a received NL character is translated into a CR character. If IGNCR is set, a received CR character is ignored (not read). Otherwise, if ICRNL is set, a received CR character is translated into a NL character.

If IUCLC is set, a received uppercase alphabetic character is translated into the corresponding lowercase character.

If IXON is set, start/stop output control is enabled. A received STOP character will suspend output and a received START character will restart output. All start/stop characters are ignored and not read. If IXANY is set, any input character will restart output which has been suspended.

If IXOFF is set, the system will transmit START characters when the input queue is nearly empty and STOP characters when nearly full.

The initial input control value is all bits clear.

The *c_flag* field specifies the system treatment of output:

OPOST	0000001	Postprocesses output
OLCUC	0000002	Maps lowercase to uppercase on output
ONLCR	0000004	Maps NL to CR-NL on output
OCRNL	0000010	Maps CR to NL on output
ONOCR	0000020	No CR output at column 0
ONLRET	0000040	NL performs CR function
OFILL	0000100	Uses fill characters for delay
OFDEL	0000200	Fills is DEL, else NUL
NLDLY	0000400	Selects newline delays:
NL0	0	
NL1	0000400	
CRDLY	0003000	Selects carriage return delays:
CR0	0	
CR1	0001000	
CR2	0002000	
CR3	0003000	
TABDLY	0014000	Selects horizontal tab delays:
TAB0	0	
TAB1	0004000	
TAB2	0010000	
TAB3	0014000	Expands tabs to spaces
BSDLY	0020000	Selects backspace delays:
BS0	0	
BS1	0020000	
VTDLY	0040000	Selects vertical tab delays:
VT0	0	
VT1	0040000	
FFDLY	0100000	Selects form feed delays:
FF0	0	
FF1	0100000	

If OPOST is set, output characters are post-processed as indicated by the remaining flags, otherwise characters are transmitted without change.

If OLCUC is set, a lowercase alphabetic character is transmitted as the corresponding uppercase character. This function is often used in conjunction with IUCLC.

If ONLCR is set, the NL character is transmitted as the CR-NL character pair. If OCRNL is set, the CR character is transmitted as the NL character. If ONOCR is set, no CR character is transmitted when at column 0 (first position). If ONLRET is set, the NL character is assumed to perform the carriage return function and the column pointer is set to 0 and the delays specified for CR will be used. Otherwise, the NL character is assumed to perform the linefeed function; the column pointer will remain unchanged. The column pointer is also set to 0 if the CR character is actually transmitted.

The delay bits specify how long transmission stops to allow for mechanical or other movement when certain characters are sent to the terminal. In all cases, a value of 0 indicates no delay. If OFILL is set, fill characters will be transmitted for delay instead of a timed delay. This is useful for high baud rate terminals which need only a minimal delay. If OFDEL is set, the fill character is DEL, otherwise NUL.

If a form feed or vertical tab delay is specified, it lasts for about 2 seconds.

Newline delay lasts about 0.10 seconds. If ONLRET is set, the carriage return delays are used instead of the newline delays. If OFILL is set, 2 fill characters will be transmitted.

Carriage return delay type 1 is dependent on the current column position, type 2 is about 0.10 seconds, and type 3 is about 0.15 seconds. If OFILL is set, delay type 1 transmits 2 fill characters, and type 2 transmits 4 fill characters.

Horizontal tab delay type 1 is dependent on the current column position. Type 2 is about 0.10 seconds. Type 3 specifies that tabs are to be expanded into spaces. If OFILL is set, 2 fill characters will be transmitted for any delay.

Backspace delay lasts about 0.05 seconds. If OFILL is set, 1 fill character will be transmitted.

The actual delays depend on line speed and system load.

The initial output control value is all bits clear.

The *c_flag* field describes the hardware control of the terminal:

CBAUD	0000017	Baud rate:
B0	0	Hang up
B50	0000001	50 baud
B75	0000002	75 baud
B110	0000003	110 baud
B134	0000004	134.5 baud
B150	0000005	150 baud

B200	0000006	200 baud
B300	0000007	300 baud
B600	0000010	600 baud
B1200	0000011	1200 baud
B1800	0000012	1800 baud
B2400	0000013	2400 baud
B4800	0000014	4800 baud
B9600	0000015	9600 baud
EXTA	0000016	External A
EXTB	0000017	External B
CSIZE	0000060	Character size:
CS5	0	5 bits
CS6	0000020	6 bits
CS7	0000040	7 bits
CS8	0000060	8 bits
CSTOPB	0000100	Sends two stop bits, else one
CREAD	0000200	Enables receiver
PARENB	0000400	Parity enable
PARODD	0001000	Odd parity, else even
HUPCL	0002000	Hangs up on last close
CLOCAL	0004000	Local line, else dial-up

The CBAUD bits specify the baud rate. The zero baud rate, B0, is used to hang up the connection. If B0 is specified, the data-terminal-ready signal will not be asserted. Without this signal, the line is disconnected if it is connected through a modem. For any particular hardware, impossible speed changes are ignored.

The CSIZE bits specify the character size in bits for both transmission and reception. This size does not include the parity bit, if any. If CSTOPB is set, 2 stop bits are used, otherwise 1 stop bit. For example, at 110 baud, 2 stops bits are required.

If PARENB is set, parity generation and detection is enabled and a parity bit is added to each character. If parity is enabled, the PARODD flag specifies odd parity if set, otherwise even parity is used.

If CREAD is set, the receiver is enabled. Otherwise no characters will be received.

If HUPCL is set, the line will be disconnected when the last process with the line open closes it or terminates. That is, the data-terminal-ready signal will not be asserted.

If CLOCAL is set, the line is assumed to be a local, direct connection with no modem control. The data-terminal-ready and request-to-send signals are asserted, but incoming modem signals are ignored. If CLOCAL is not set, modem control is assumed. This means the data-terminal-ready and request-to-send signals are

asserted. Also, the carrier-detect signal must be returned before communications can proceed.

The initial hardware control value after open is B9600, CS8, CREAD, HUPCL.

The *c_lflag* field of the argument structure is used by the line discipline to control terminal functions. The basic line discipline (0) provides the following:

ISIG	0000001	Enable signals
ICANON	0000002	Canonical input (erase and kill processing)
XCASE	0000004	Canonical upper/lower presentation
ECHO	0000010	Enables echo
ECHOE	0000020	Echoes erase character as BS-SP-BS
ECHOK	0000040	Echoes NL after kill character
ECHONL	0000100	Echoes NL
NOFLSH	0000200	Disables flush after interrupt or quit
XCLUDE	0100000	Exclusive use of the line

If ISIG is set, each input character is checked against the special control characters INTR and QUIT. If an input character matches one of these control characters, the function associated with that character is performed. If ISIG is not set, no checking is done. Thus, these special input functions are possible only if ISIG is set. These functions may be disabled individually by changing the value of the control character to an unlikely or impossible value (e.g., 0377).

If ICANON is set, canonical processing is enabled. This enables the erase and kill edit functions, and the assembly of input characters into lines delimited by NL, EOF, and EOL. If ICANON is not set, read requests are satisfied directly from the input queue. A read will not be satisfied until at least VMIN characters have been received or the timeout value VTIME has expired and a character has been input. This allows fast bursts of input to be read efficiently while still allowing single character input. The VMIN and VTIME values are stored in the position for the EOF and EOL characters respectively. VMIN and VTIME are interpreted as EOF and EOL if ICANON is set. Default VMIN and VTIME values can be changed in the */usr/include/sys/termio.h* file. The time value represents tenths of seconds.

If XCASE and ICANON are set, an uppercase letter is accepted on input by preceding it with a \ character, and is output preceded by a \ character. In this mode, the following escape sequences are generated on output and accepted on input:

For:	Use:
`	\`
	\!
~	\~
{	\{
}	\}
\	\\

For example, A is input as `\a`, `\n` as `\\n`, and `\\N` as `\\\\n`.

If ECHO is set, characters are echoed as received.

When ICANON is set, the following echo functions are possible. If ECHO and ECHOE are set, the erase character is echoed as ASCII BS SP BS, which will clear the last character from a CRT screen. If ECHOE is set and ECHO is not set, the erase character is echoed as ASCII SP BS. If ECHOK is set, the NL character will be echoed after the kill character to emphasize that the line will be deleted. Note that an escape character preceding the erase or kill character removes any special function. If ECHONL is set, the NL character will be echoed even if ECHO is not set. This is useful for terminals set to local echo (so-called half duplex). Unless escaped, the EOF character is not echoed. Because EOT is the default EOF character, this prevents terminals that respond to EOT from hanging up.

If NOFLSH is set, the normal flush of the input and output queues associated with the quit and interrupt characters will not be done.

If XCLUDE is set, any subsequent attempt to open the TTY device using `open(S)` will fail for all users except the super-user. If the call fails, it returns EBUSY in `errno`. XCLUDE is useful for programs which must have exclusive use of a communications line. It is not intended for the line to the program's controlling terminal. XCLUDE must be cleared before the setting program terminates, otherwise subsequent attempts to open the device will fail.

The initial line-discipline control value is all bits clear.

The primary `ioctl(S)` system calls have the form:

```
ioctl (fildes, command, arg)
struct termio *arg;
```

The commands using this form are:

TCGETA	Gets the parameters associated with the terminal and stores them in the <i>termio</i> structure referenced by arg .
TCSETA	Sets the parameters associated with the terminal from the structure referenced by arg . The change is immediate.

- TCSETAW Waits for the output to drain before setting the new parameters. This form should be used when changing parameters that will affect output.
- TCSETAF Waits for the output to drain, then flushes the input queue and sets the new parameters.

Additional *ioctl*(S) calls have the form:

```
ioctl (fildes, command, arg)
int arg;
```

The commands using this form are:

- TCSBRK Waits for the output to drain. If *arg* is 0, then sends a break (zero bits for 0.25 seconds).
- TCXONC Starts/stops control. If *arg* is 0, suspends output; if 1, restarts suspended output.
- TCFLSH If *arg* is 0, flushes the input queue; if 1, flushes the output queue; if 2, flushes both the input and output queues.

Name

`top`, `top.next` – The Micnet topology files.

Description

These files contain the topology information for a Micnet network. The topology information describes how the individual systems in the network are connected, and what path a message must take from one system to reach another. Each file contains one or more lines of text. Each line of text defines a connection or a communication path.

The `top` file defines connections between systems. Each line lists the machine names of the connected systems, the serial lines used to make the connection, and the speed (baud rate) of transmission between the systems. Each line has the following format:

```
machine1 tty1a machine2 tty2a speed
```

machine1 and *machine2a* are the machine names of the respective systems (as given in the `systemid` files). The *tty*s are the device names (e.g., `tty1a`) of the connecting serial lines. The speed must be an acceptable baud rate (e.g., 110, 300, ..., 19200).

The `top.next` file contains information about how to reach a particular system from a given system. There may be several lines for each system in the network. Each line lists the machine name of a system, followed by the machine name of a system connected to it, followed by the machine names of all the systems that may be reached by going through the second system. Such a line has the form:

```
machine1 machine2 machine3 [machine4]...
```

The machine names must be the names of the respective systems (as given by the first machine name in the `systemid` files).

The `top.next` file must be present even if there are only two computers in the network. In such a case, the file must be empty.

In the `top` and `top.next` files, any line beginning with a number sign (#) is considered a comment, and is ignored.

Files

```
/usr/lib/mail/top
```

```
/usr/lib/mail/top.next
```

TOP (M)

TOP (M)

See Also

aliases(M), netutil(C), systemid(M), top(M)

Name

tty – Special terminal interface.

Description

The file `/dev/tty` is, in each process, a synonym for the control terminal associated with the process group of that process, if any. It is useful for programs or shell sequences that wish to be sure of writing messages on the terminal no matter how output has been redirected. It can also be used for programs that demand the name of a file for output, when typed output is desired, and when it is tiresome to find out what terminal is currently in use.

The general terminal interface is described in *termio*(M).

Files

`/dev/tty`
`/dev/tty*`

See Also

termio(M)

Name

ttys – Login terminals file.

Description

The */etc/ttys* file contains a list of the device special files associated with possible login terminals, and defines which files are to be opened by the *init*(M) program on system start-up.

The file contains one or more entries of the form

state mode name

The *name* must be the filename of a device special file. Only the filename may be supplied, the path is assumed to be */dev*. If *state* is “1”, the file is enabled for logins; if “0”, the file is disabled. The *mode* is used as an argument to the *getty*(M) program. It defines the line speed and type of device associated with the terminal. A list of arguments is provided in *getty*(M).

For example, the entry “1mtty02” means the serial line tty02 is to be opened for logging in at 9600 baud.

Files

/etc/ttys

See Also

init(M), *getty*(M), *enable*(C), *disable*(C)

Notes

The */etc/ttys* file should only be edited when the system is in system maintenance mode. If it is edited when the system is in multi-user mode, the changes will not take effect until the system is rebooted, or until an *enable* or *disable* command is given. See the *XENIX Operations Guide*.

Name

TZ – Time zone shell variable.

Syntax

```
TZ= xxxnzzz ; export TZ
```

```
setenv TZ xxxnzzz
```

```
/etc/tz
```

Description

TZ is the shell environment variable for the time zone of the system and is set in the files */etc/rc* and */etc/default/login*.

The shell script */etc/tz*, generally run during installation, prompts for the correct time zone and makes the changes in the appropriate files.

Users living in a time zone different than that of the host machine may change TZ in their *\$HOME/.profile* or *\$HOME/.login* files.

TZ contains the following information:

- (xxx) Three uppercase letters designating the time zone.
- (n) Number of hours past Greenwich mean time.
- (zzz) Three uppercase letters designating the local daylight savings time zone.

For Eastern Standard/Daylight Time TZ is set as follows:

```
TZ=EST5EDT ; export TZ  
(for sh(C) and vsh(C))
```

```
setenv TZ EST5EDT  
(for csh(C))
```

To change the time zone for the entire system, run the shell script */etc/tz* (as root) or use an editor to change the variable TZ in the files */etc/rc* and */etc/default/login*. In */etc/rc* the line changing the time zone (see the *sh* example above) must occur before the */etc/asktime* command. The TZ variable in */etc/default/login* causes the time zone to be set correctly on logging in and for programs such as *uucico*.

TZ (M)

TZ (M)

Files

/etc/rc
/etc/default/login
/etc/tz
\$HOME/.profile
\$HOME/.login

environ(M), date(C), ctime(S)

Notes

The *date*(C) automatically switches from Standard Time to Daylight Savings Time.

Name

utmp, wtmp – Formats of utmp and wtmp entries.

Syntax

```
#include <sys/types.h>
#include <utmp.h>
```

Description

These files, which hold user and accounting information for such commands as *who*(C), *write*(C), and *login*(M), have the following structure as defined by <utmp.h>:

```
#define  UTMP_FILE    "/etc/utmp"
#define  WTMP_FILE    "/etc/wtmp"
#define  ut_name      ut_user

struct utmp {
    char    ut_user[8];        /* User login name */
    char    ut_id[4];         /* usually line # */
    char    ut_line[12];      /* device name (console, lxxx) */
    short   ut_pid;           /* process id */
    short   ut_type;          /* type of entry */
    struct  exit_status {
        short   e_termination; /* Process termination status */
        short   e_exit;        /* Process exit status */
    } ut_exit;                /* The exit status of a process
                               marked as DEAD_PROCESS. */
    time_t   ut_time;         /* time entry was made */
};

/* Definitions for ut_type */

Name

intro - Introduction to file formats.

Description

This section outlines the formats of various files. Usually, these structures can be found in the directories **/usr/include** or **/usr/include/sys**.

Name

86rel – Intel 8086 Relocatable Format for Object Modules.

Syntax

```
#include <sys/reldsym86.h>
```

Description

Intel 8086 Relocatable Format, or *86rel*, is the object module format generated by *masm*(CP), and the input format for the linker *ld*(CP). The include file **reldsym86.h** specifies appropriate definitions to access *86rel* format files from C. For the technical details of the *86rel* format, see *Intel 8086 Object Module Format External Product Specification*.

An *86rel* consists of one or more variable length records. Each record has at least three fields: the record type, length, and checksum. The first byte always denotes the record type. There are thirty-one different record types. Only eleven are used by *ld*(CP) and *masm*(CP). The word after the first byte is the length of the record in bytes, exclusive of the first three bytes. Following the length word are typically one or more fields. Each record type has a specific sequence of fields, some of which may be optional or of varying length. The very last byte in each record is a checksum. The checksum byte contains the sum modulo 256 of all other bytes in the record. The sum modulo 256 of all bytes in a record, including the checksum byte, should equal zero.

With few exceptions, *86rel* strings are length prefixed and have no trailing null. The first byte contains a number between 0 and 40, which is the remaining length of the string in bytes. Although the Intel specification limits the character set to upper case letters, digits, and the characters “?”, “@”, “:”, “.”, and “_”, *masm*(CP) uses the complete ASCII character set.

The Intel Object Module Format (OMF) specification uses the term “index” to mean a positive integer either in the range 0 to 127, or 128 to 32,768. This terminology is retained in this document and elsewhere in the *86rel* literature. An index has one or two bytes. If the first byte has a leading 0 bit, the index is assumed to have only one byte, and the remainder of the byte represents a positive integer between 0 and 127. If the second byte has a leading 1 bit, the index is assumed to take up two bytes, and the remainder of the word represents a positive integer between 128 and 32,768.

Following is a list of record types and the hexadecimal value of their first byte, as defined in **reldsym86.h**.

```

#define MRHEADR    0x6e /*rel module header*/
#define MREGINT    0x70 /*register initialization*/
#define MREDATA    0x72 /*explicit (enumerated) data image*/
#define MRIDATA    0x74 /*repeated (iterated) data image*/
#define MOVLDEF    0x76 /*overlay definition*/
#define MENDREC    0x78 /*block or overlay end record*/
#define MBLKDEF    0x7a /*block definition*/
#define MBLKEND    0x7c /*block end*/
#define MDEBSYM    0x7e /*debug symbols*/
#define MTHEADR    0x80 /*module header,
                        *usually first in a rel file*/
#define MLHEADR    0x82 /*link module header*/
#define MPEDATA    0x84 /*absolute data image*/
#define MPIDATA    0x86 /*absolute repeated (iterated)
                        *data image*/
#define MCOMENT    0x88 /*comment record*/
#define MMODEND    0x8a /*module end record*/
#define MEXTDEF    0x8c /*external definition*/
#define MTYPDEF    0x8e /*type definition*/
#define MPUBDEF    0x90 /*public definition*/
#define MLOCSYM    0x92 /*local symbols*/
#define MLINNUM    0x94 /*source line number*/
#define MLNAMES    0x96 /*name list record*/
#define MSEGDEF    0x98 /*segment definition*/
#define MGRPDEF    0x9a /*group definition*/
#define MFXUPP    0x9c /*fix up previous data image*/
#define MNONE1     0x9e /*none*/
#define MLEDATA    0xa0 /*logical data image*/
#define MLIDATA    0xa2 /*logical repeated (iterated)
                        *data image*/
#define MLIBHED    0xa4 /*library header*/
#define MLIBNAM    0xa6 /*library names record*/
#define MLIBLOC    0xa8 /*library module locations*/
#define MLIBDIC    0xaa /*library dictionary*/

```

In the following discussion, the salient features of each record type are given. If the record is not used by either *masm*(CP) or *ld*(CP), it is not listed.

THEADR The record type byte is 0x80. The THEADR record specifies the name of the source module at assembly-time (see Notes). The sole field is the T-MODULE NAME , which contains a length-prefixed string derived from the base name of the source module.

COMENT The record type byte is 0x88. The COMENT record may contain a remark generated by the compiler system. *masm*(CP) inserts the string "XENIX 8086 ASSEMBLER."

MODEND	The record type byte is 0x8a. The MODEND record terminates a module. It can specify whether the current module is to be used as the entry point to the linked executable. If the module is an entry point, the MODEND record can then specify the address of the entry point within the executable.
EXTDEF	The record type byte is 0x8c. The EXTDEF record contains the names and types of symbols defined in other modules by a PUBDEF record (see below). This corresponds to the C storage class "extern." The fields consist of one or more length-prefixed strings, each with a following type index. The indices reference a TYPDEF record seen earlier in the module. <i>masm</i> (CP) generates only one EXTDEF per exterior symbol.
TYPDEF	The record type byte is 0x8e. The TYPDEF record gives a description of the type (size and storage attributes) of an object or objects. This description can then be referenced by EXTDEF , PUBDEF , and other records?
PUBDEF	The record type byte is 0x90. The PUBDEF record gives a list of one or more names that may be referenced by other modules at link-time ("publics"). The list of names is preceded by a group and segment index, which reference the location of the start of the list of publics within the current segment and group. If the segment and group indices are zero, a frame number is given to provide an absolute address in the module. The list consists of one or more of length-prefixed strings, each associated with a 16-bit offset within the current segment and a type index referring to a TYPDEF .
LNAMES	The record type byte is 0x96. The LNAMES record gives a series of length-prefixed strings which are associated with name indices within the current module. Each name is indexed in sequence given starting with 1. The names may then be referenced within the current module by successive SEGDEF and GRPDEF records to provide strings for segments, classes, overlays or groups.
SEGDEF	The record type byte is 0x98. The SEGDEF record provides an index to reference a segment, and information concerning segment addressing and attributes. This index may be used by other records to refer to the segment. The first word in the record after the length field gives information about the alignment, and about combination attributes of the segment.

The next word is the segment length in bytes. Note that this restrains segments to a maximum 645,536 bytes in length. Following this word is an index (see above) for the segment. Lastly, the SEGDEF may optionally contain class and/or overlay index fields.

- GRPDEF The record type is 0x9a. The GRPDEF record provides a name to reference several segments. The group name is implemented as an index (see above).
- FIXUPP The record byte is 0x9c. The FIXUPP record specifies one or more load-time address modifications ("fixups"). Each fixup refers to a location in a preceeding LEDATA (see below) record. The fixup is specified by four data; a location, a mode, a target and a frame. The frame and target may be specified explicitly or by reference to an already defined fixup.
- LEDATA The record type byte is 0xa0. This record provides a contiguous text or data image which the loader *ld*(CP) uses to construct a portion of an 8086 run-time executable. The image might require additional processing (see FIXUPP) before being loaded into the executable. The image is preceeded by two fields, a segment index and an enumerated data offset. The segment index (see INDEX) specifies a segment given by a previously seen SEGDEF. The enumerated data offset (a word) specifies the offset from the start of this segment.

See Also

as(CP), ld(CP)

Notes

If you attempt to load a number of modules assembled under the same basename, the loader will try to put them all in one big segment. Segment size is limited to 64K. In a large program the resulting segment size can easily exceed 64K. A large model code executable results from the link of one or more modules, composed of segments that aggregate into greater than 64K of text.

Hence, be sure that the assembly-time name of the module has the same basename as the source. This can occur if the source module is preprocessed not by *cc*(CP), but, for example, by hand or shell script, prior to assembly. The following example is incorrect:

```
#incorrect
cc -E module1.c | filter > x.c
cc x.c
mv x.o module1.o
cc -E module2.c | filter > x.c
cc x.c
mv x.o module2.o
cc -E module3.c | filter > x.c
cc x.c
mv x.o module3.o
ld module1.o module2.o module3.o
```

To avoid this, each of the modules should have a unique name when assembled, as follows:

```
#correct
cc -E module1.c | filter > x.c
cc -S x.c
mv x.s module1.s
as module1.s
.
.
.
ld module1.o module2.o module3.o
```

Name

a.out – Format of assembler and link editor output.

Description

a.out is the output file of the assembler *masm* and the link editor *ld*. Both programs will make *a.out* executable if there were no errors in assembling or linking, and no unresolved external references.

The format of *a.out*, called the *x.out* or segmented *x.out* format, is defined by the files `/usr/include/a.out.h` and `/usr/include/sys/relsym.h`. The *a.out* file has the following general layout:

1. Header.
2. Extended header.
3. File segment table (for segmented formats).
4. Segments (Text, Data, Symbol, and Relocation).

In the segmented format, there may be several text and data segments, depending on the memory model of the program. Segments within the file begin on boundaries which are multiplies of 512 bytes as defined by the file's pagesize.

Format

```
/*
 * The main and extended header structures.
 * For x.out segmented (XE_SEG):
 * 1) fields marked with (s) must contain sums of xs_psize for
 *    non-memory images, or xs_vsize for memory images.
 * 2) the contents of fields marked with (u) are undefined.
 */

struct xexec {          /* x.out header */
    unsigned short  x_magic; /* magic number */
    unsigned short  x_ext;   /* size of header extension */
    long            x_text;  /* size of text segment (s) */
    long            x_data;   /* size of initialized data (s) */
    long            x_bss;    /* size of uninitialized data (s) */
    long            x_syms;   /* size of symbol table (s) */
    long            x_reloc;  /* relocation table length (s) */
    long            x_entry;  /* entry point, machine dependent */
}
```

```

char    x_cpu;    /* cpu type & byte/word order */
char    x_relsym; /* relocation & symbol format (u) */
unsigned short x_renv; /* run-time environment */
};

struct xext {
    /* x.out header extension */
    long    xe_trsize; /* size of text relocation (s) */
    long    xe_drsz; /* size of data relocation (s) */
    long    xe_tbase; /* text relocation base (u) */
    long    xe_dbase; /* data relocation base (u) */
    long    xe_stksize; /* stack size (if XE_FS set) */
    /* the following must be present if XE_SEG */
    long    xe_segpos; /* segment table position */
    long    xe_segsize; /* segment table size */
    long    xe_mdtpos; /* machine dependent table position */
    long    xe_mdtsz; /* machine dependent table size */
    char    xe_mdttpe; /* machine dependent table type */
    char    xe_pagesize; /* file pagesize, in multiples of 512 */
    char    xe_ostype; /* operating system type */
    char    xe_osvers; /* operating system version */
    unsigned short xe_eseg; /* entry segment, machine dependent */
    unsigned short xe_sres; /* reserved */
};

struct xseg {
    /* x.out segment table entry */
    unsigned short xs_type; /* segment type */
    unsigned short xs_attr; /* segment attributes */

Name

acct – Format of per-process accounting file.

Description

Files produced as a result of calling *acct*(S) have records in the form defined by `<sys/acct.h>`.

In *ac_flag*, the AFORK flag is turned on by each *fork*(S) and turned off by an *exec*(S). The *ac_comm* field is inherited from the parent process and is reset by any *exec*. Each time the system charges the process with a clock tick, it also adds the current process size to *ac_mem* computed as follows:

$$(\text{data size}) + (\text{text size}) / (\text{number of in-core processes using text})$$

The value of *ac_mem/ac_stime* can be viewed as an approximation to the mean process size, as modified by text-sharing.

See Also

acct(C), acctcom(C), acct(S)

Notes

The *ac_mem* value for a short-lived command gives little information about the actual size of the command, because *ac_mem* may be incremented while a different command (e.g., the shell) is being executed by the process.

Name

ar – Archive file format.

Description

The archive command *ar* is used to combine several files into one. Archives are used mainly as libraries to be searched by the link editor *ld*(C).

A file produced by *ar* has a magic number at the start, followed by the constituent files, each preceded by a file header. The magic number is 0177545 octal (or 0xff65 hexadecimal). The header of each file is declared in `/usr/include/ar.h`.

Each file begins on a word boundary; a null byte is inserted between files if necessary. Nevertheless the size given reflects the actual size of the file exclusive of padding.

Notice there is no provision for empty areas in an archive file.

ar(CP), ld(CP)

Name

backup – Incremental dump tape format.

Description

The *backup* and *restore* commands are used to write and read incremental dump magnetic tapes.

The backup tape consists of a header record, some bit mask records, a group of records describing file system directories, a group of records describing file system files, and some records describing a second bit mask.

The header record and the first record of each description have the format described by the structure included by:

```
#include <dumprestor.h>
```

Fields in the *dumprestor* structure are described below.

NTREC is the number of 512 byte blocks in a physical tape record. MLEN is the number of bits in a bit map word. MSIZ is the number of bit map words.

The TS_ entries are used in the *c_type* field to indicate what sort of header this is. The types and their meanings are as follows:

TS_TYPE	Tape volume label.
TS_INODE	A file or directory follows. The <i>c_dinode</i> field is a copy of the disk inode and contains bits telling what sort of file this is.
TS_BITS	A bit mask follows. This bit mask has one bit for each inode that was backed up.
TS_ADDR	A subblock to a file (<i>TS_INODE</i>). See the description of <i>c_count</i> below.
TS_END	End of tape record.
TS_CLRI	A bit mask follows. This bit mask contains one bit for all inodes that were empty on the file system when backed up.
MAGIC	All header blocks have this number in <i>c_magic</i> .
CHECKSUM	Header blocks checksum to this value.

The fields of the header structure are as follows:

c_type	The type of the header.
c_date	The date the backup was taken.
c_ddate	The date the file system was backed up.
c_volume	The current volume number of the backup.
c_tapea	The current block number of this record. This is counting 512 byte blocks.
c_inumber	The number of the inode being backed up if this is of type TS_INODE.
c_magic	This contains the value MAGIC above, truncated as needed.
c_checksum	This contains whatever value is needed to make the block sum to CHECKSUM.
c_dinode	This is a copy of the inode as it appears on the file system.
c_count	The following count of characters describes the file. A character is zero if the block associated with that character was not present on the file system; otherwise, the character is nonzero. If the block was not present on the file system no block was backed up and it is replaced as a hole in the file. If there is not sufficient space in this block to describe all of the blocks in a file, TS_ADDR blocks will be scattered through the file, each one picking up where the last left off.
c_addr	This is the array of characters that is used as described above.

Each volume except the last ends with a tapemark (read as an end of file). The last volume ends with a TS_END block and then the tapemark.

The structure *idates* describes an entry of the file where backup history is kept.

Name

checklist – List of file systems processed by *fsck*.

Description

The */etc/checklist* file contains a list of the file systems to be checked when *fsck*(C) is invoked without arguments. The list contains at most 15 **special file** names. Each **special file** name must be on a separate line and must correspond to a file system.

See Also

fsck(C)

Name

core – Format of core image file.

Description

XENIX writes out a core image of a terminated process when any of various errors occur. See *signal(S)* for the list of reasons; the most common are memory violations, illegal instructions, bus errors, and user-generated quit signals. The core image is called *core* and is written in the process' working directory (provided it can be; normal access controls apply). A process with an effective user ID different from the real user ID will not produce a core image.

The first section of the core image is a copy of the system's per-user data for the process, including the registers as they were at the time of the fault. The size of this section depends on the parameter *usize*, which is defined in */usr/include/sys/param.h*. The remainder represents the actual contents of the user's core area when the core image was written. If the text segment is read-only and shared, or separated from data space, it is not dumped.

The format of the information in the first section is described by the *user* structure of the system, defined in */usr/include/sys/user.h*. The locations of registers, are outlined in */usr/include/sys/reg.h*.

adb(CP), setuid(S), signal(S)

Name

cpio - Format of cpio archive.

Description

The *header* structure, when the `c` option is not used, is:

```

struct {
    short    h_magic,
            h_dev,
            h_ino,
            h_mode,
            h_uid,
            h_gid,
            h_nlink,
            h_rdev,
            h_mtime[2],
            h_namesize,
            h_filesiz[2];
    char     h_name[h_namesize rounded to word];
} Hdr;

```

When the **c** option is used, the *header* information is described by the statement below:

```
sscanf(Chdr,"%6o%6o%6o%6o%6o%6o%6o%6o%6o%6o%6o%6o%11lo%6o%6o%s",  
      &Hdr.h_magic,&Hdr.h_dev,&Hdr.h_ino,&Hdr.h_mode,  
      &Hdr.h_uid,&Hdr.h_gid,&Hdr.h_nlink,&Hdr.h_rdev,  
      &Longtime,&Hdr.h_namesize,&Longfile,Hdr.h_name);
```

Longtime and *Longfile* are equivalent to *Hdr.h_mtime* and *Hdr.h_filesize*, respectively. The contents of each file is recorded in an element of the array of varying length structures, *archive*, together with other items describing the file. Every instance of *h_magic* contains the constant 070707 (octal). The items *h_dev* through *h_mtime* have meanings explained in *stat(S)*. The length of the null-terminated pathname *h_name*, including the null byte, is given by *h_namesize*.

The last record of the *archive* always contains the name TRAILER!!!. Special files, directories, and the trailer are recorded with *h_filesize* equal to zero.

See Also

cpio(C), find(C), stat(S)

Name

dir – Format of a directory.

Syntax

```
#include <sys/dir.h>
```

Description

A directory behaves exactly like an ordinary file, except that no user may write into a directory. The fact that a file is a directory is indicated by a bit in the flag word of its inode entry (see *filesystem(F)*). The structure of a directory is given in the include file */usr/include/sys/dir.h*.

By convention, the first two entries in each directory are “dot” (.) and “dotdot” (..). The first is an entry for the directory itself. The second is for the parent directory. The meaning of dotdot is modified for the root directory of the master file system; there is no parent, so dotdot has the same meaning as dot.

filesystem(F)

Name

dump – Incremental dump tape format.

Description

The *dump* and *restor* commands are used to write and read incremental dump magnetic tapes.

The dump tape consists of a header record, some bit mask records, a group of records describing file system directories, a group of records describing file system files, and some records describing a second bit mask.

The header record and the first record of each description have the format described by the structure included by:

```
#include <dumprestor.h>
```

Fields in the *dumprestor* structure are described below.

NTREC is the number of 512 byte blocks in a physical tape record. MLEN is the number of bits in a bit map word. MSIZ is the number of bit map words.

The TS_ entries are used in the *c_type* field to indicate what sort of header this is. The types and their meanings are as follows:

TS_TYPE	Tape volume label.
TS_INODE	A file or directory follows. The <i>c_dinode</i> field is a copy of the disk inode and contains bits telling what sort of file this is.
TS_BITS	A bit mask follows. This bit mask has a one-bit for each inode that was dumped.
TS_ADDR	A subblock to a file (<i>TS_INODE</i>). See the description of <i>c_count</i> below.
TS_END	End of tape record.
TS_CLRI	A bit mask follows. This bit mask contains a one-bit for all inodes that were empty on the file system when dumped.
MAGIC	All header blocks have this number in <i>c_magic</i> .
CHECKSUM	Header blocks checksum to this value.

The fields of the header structure are as follows:

c_type	The type of the header.
c_date	The date the dump was taken.
c_ddate	The date the file system was dumped from.
c_volume	The current volume number of the dump.
c_tapea	The current block number of this record. This is counting 512 byte blocks.
c_inumber	The number of the inode being dumped if this is of type TS_INODE.
c_magic	This contains the value MAGIC above, truncated as needed.
c_checksum	This contains whatever value is needed to make the block sum to CHECKSUM.
c_dinode	This is a copy of the inode as it appears on the file system.
c_count	This is the count of characters following that describe the file. A character is zero if the block associated with that character was not present on the file system, otherwise the character is nonzero. If the block was not present on the file system no block was dumped and it is replaced as a hole in the file. If there is not sufficient space in this block to describe all of the blocks in a file, TS_ADDR blocks will be scattered through the file, each one picking up where the last left off.
c_addr	This is the array of characters that is used as described above.

Each volume except the last ends with a tapemark (read as an end of file). The last volume ends with a TS_END block and then the tapemark.

The structure *idates* describes an entry of the file where dump history is kept.

Name

file system – Format of a system volume.

Syntax

```
#include <sys/filsys.h>
#include <sys/types.h>
#include <sys/param.h>
```

Description

Every file system storage volume (for example, a hard disk) has a common format for certain vital information. Every such volume is divided into a certain number of 256 word (512 byte) blocks. Block 0 is unused and is available to contain a bootstrap program or other information.

Block 1 is the *super-block*. The format of a super-block is described in */usr/include/sys/filesys.h*. In that include file, *S_ysize* is the address of the first data block after the i-list. The i-list starts just after the super-block in block 2; thus the i-list is *s_ysize-2* blocks long. *S_fsize* is the first block not potentially available for allocation to a file. These numbers are used by the system to check for bad block numbers. If an “impossible” block number is allocated from the free list or is freed, a diagnostic is written on the console. Moreover, the free array is cleared so as to prevent further allocation from a presumably corrupted free list.

The free list for each volume is maintained as follows. The *s_free* array contains, in *s_free[1]*, . . . , *s_free[s_nfree-1]*, up to 49 numbers of free blocks. *S_free[0]* is the block number of the head of a chain of blocks constituting the free list. The first long in each free-chain block is the number (up to 50) of free-block numbers listed in the next 50 longs of this chain member. The first of these 50 blocks is the link to the next member of the chain. To allocate a block: decrement *s_nfree*, and the new block is *s_free[s_nfree]*. If the new block number is 0, there are no blocks left, so give an error. If *s_nfree* becomes 0, read in the block named by the new block number, replace *s_nfree* by its first word, and copy the block numbers in the next 50 longs into the *s_free* array. To free a block, check if *s_nfree* is 50; if so, copy *s_nfree* and the *s_free* array into it, write it out, and set *s_nfree* to 0. In any event set *s_free[s_nfree]* to the freed block's number and increment *s_nfree*.

S_tfree is the total free blocks available in the file system.

S_ninode is the number of free i-numbers in the *s_inode* array. To allocate an inode: if *s_ninode* is greater than 0, decrement it and return *s_inode[s_ninode]*. If it was 0, read the i-list and place the

numbers of all free inodes (up to 100) into the *s_inode* array, then try again. To free an inode, provided *s_ninode* is less than 100, place its number into *s_inode[s_ninode]* and increment *s_ninode*. If *s_ninode* is already 100, do not bother to enter the freed inode into any table. This list of inodes only speeds up the allocation process. The information about whether the inode is really free is maintained in the inode itself.

S_tinode is the total free inodes available in the file system.

S_flock and *s_iloc* are flags maintained in the core copy of the file system while it is mounted and their values on disk are immaterial. The value of *s_fmod* on disk is also immaterial, and is used as a flag to indicate that the super-block has changed and should be copied to the disk during the next periodic update of file system information.

S_ronly is a read-only flag to indicate write-protection.

S_time is the last time the super-block of the file system was changed, and is a double precision representation of the number of seconds that have elapsed since 00:00 Jan. 1, 1970 (GMT). During a reboot, the *s_time* of the super-block for the root file system is used to set the system's idea of the time.

I-numbers begin at 1, and the storage for inodes begins in block 2. Also, inodes are 64 bytes long, so 8 of them fit into a block. Therefore, inode *i* is located in block $(i+15)/8$, and begins $64 \times ((i+15) \bmod 8)$ bytes from its start. Inode 1 is reserved for future use. Inode 2 is reserved for the root directory of the file system, but no other i-number has a built-in meaning. Each inode represents one file. For the format of an inode and its flags, see *inode(F)*.

Name

gettydefs – Speed and terminal settings used by getty.

Description

The */etc/gettydefs* file contains information used by *getty*(M) to set up the speed and terminal settings for a line. It supplies information on what the *login* prompt should look like. It also supplies the speed to try next if the user indicates the current speed is not correct by typing a BREAK character.

Each entry in */etc/gettydefs* has the following format:

```
label# initial-flags # final-flags # login-prompt #next-label [#
login-program]
```

Each entry is followed by a blank line. The various fields can contain quoted characters of the form *\b*, *\n*, *\c*, etc., as well as *\nnn*, where *nnn* is the octal value of the desired character. The various fields are:

<i>label</i>	Identifies the <i>/etc/gettydefs</i> entry to <i>getty</i> . This could be a letter or number. The label corresponds to the line mode field in <i>/etc/ttys</i> . <i>Init</i> passes the line mode as an argument to <i>getty</i> .
<i>initial-flags</i>	Sets the initial <i>ioctl</i> (S) settings if a terminal type is not specified to <i>getty</i> . The flags that <i>getty</i> understands are the same as the ones listed in <i>tty</i> (M). Normally only the speed flag is required in the <i>initial-flags</i> . <i>Getty</i> automatically sets the terminal to raw input mode and takes care of most of the other flags. The <i>initial-flag</i> settings remain in effect until <i>getty</i> executes <i>login</i> (M).
<i>final-flags</i>	Sets the same values as the <i>initial-flags</i> . These flags are set just prior to <i>getty</i> executing <i>login-program</i> . The speed flag is again required. The composite flag SANE takes care of most of the other flags that need to be set so that the processor and terminal are communicating in a rational fashion. The other two commonly specified <i>final-flags</i> are TAB3 , so that tabs are sent to the terminal as spaces, and HUPCL , so that the line is hung up on the final close.
<i>login-prompt</i>	Contains login prompt message that greets users. Unlike the above fields where white space is ignored (a space, tab, or new-line), it is included in the <i>login-prompt</i> field. The '@' in the login-prompt

field is expanded to the first line in */etc/systemid* (unless the '@' is preceded by a '\'). Several character sequences are recognized, including:

```
\n      Linefeed
\r      Carriage return
\v      Vertical tab
\nnn    (3 octal digits) Specify ASCII character
\*       Tab
\f       Form feed
\b       Backspace
```

next-label Identifies the next entry in *gettydefs* for *getty* to try if the current one is not successful. *Getty* tries the next label if a user presses the BREAK key while attempting to log in to the system. Groups of entries, for example, for dial-up lines or for TTY lines, should form a closed set so that *getty* cycles back to the original entry if none of the entries is successful. For instance, **2400** linked to **1200**, which in turn is linked to **300**, which finally is linked to **2400**.

login-program The name of the program that actually logs the user onto XENIX. The default program is */etc/login*. If preceded by the keyword *AUTO*, *getty* will not prompt for a username, but instead uses its first argument as the username and executes the *login-program* immediately.

If *getty* is called without a second argument, then the first entry of */etc/gettydefs* is used, thus making the first entry of */etc/gettydefs* the default entry. The first entry is also used if *getty* can not find the specified *label*. If */etc/gettydefs* itself is missing, there is one entry built into the command which will bring up a terminal at 300 baud.

After modifying */etc/gettydefs*, run it through *getty* with the check option to be sure there are no errors.

Name

inode – Format of an inode.

Syntax

```
#include <sys/types.h>  
#include <sys/ino.h>
```

Description

An inode for a plain file or directory in a file system has the structure defined by `<sys/ino.h>`. For the meaning of the defined types `off_t` and `time_t` see `types(F)`.

Files

/usr/include/sys/ino.h

See Also

stat(S), filesystem(F), types(F)

Name

master – Master device information table.

Description

This file is used by the *config*(CP) program to obtain device information that enables it to generate the configuration files. The file consists of 4 parts, each separated by a line with a dollar sign (\$) in column 1. Part 1 contains device information; part 2 contains the line discipline table; part 3 contains names of devices that have aliases; and part 4 contains tunable parameter information. Any line with an asterisk (*) in column 1 is treated as a comment.

Part 1

This part contains definitions for the system devices. Each line has 14 fields with the fields delimited by tabs and/or blanks:

Field 1: device name (8 chars. maximum).
 Field 2: number of interrupt vectors
 Field 3: device mask (octal). Each "on" bit indicates that the driver has the corresponding handler or structure:

000400 not used
 000200 not used
 000100 initialization handler
 000040 clock time poll routine
 000020 open handler
 000010 close handler
 000004 read handler
 000002 write handler
 000001 ioctl handler.

The clock time poll routine, if present in the driver, is called every clock tick in which the clock interrupted task-time processing.

Field 4: device type indicator (octal):
 000200 not used
 000040 not used
 000020 required device
 000010 block device
 000004 character device
 000002 not used
 000001 not used.

Field 5: handler prefix (4 chars. maximum). Usually same as Field 1. The routines of *dev.c* should begin *dev...*

Field 6: not used.

- Field 7: major device number for block-type device.
- Field 8: major device number for character-type device.
- Field 9: maximum number of devices per controller (decimal).
- Field 10: The *spl* level (5 - 7) at which the device's interrupt routine should be called.
- Fields 11-14: maximum of four interrupt vector addresses. Each address is followed by a unique letter or a blank.

Devices that are not interrupt-driven have an interrupt vector size of zero. Devices which generate interrupts but are not of the standard character or block device mold, should be specified with a type (field 4) which has neither the block nor character bits set.

Part 2

This part contains definitions for the system line discipline. Each line has 9 fields. Each field is a maximum of 8 characters delimited by a blank if less than 8:

- Field 1: Device associated with this line
- Field 2: Open routine
- Field 3: Close routine
- Field 4: Read routine
- Field 5: Write routine
- Field 6: Ioctl routine
- Field 7: Receiver interrupt routine
- Field 8: Transmitter interrupt routine
- Field 9: Modem control interrupt routine

Part 3

This part contains definitions for device aliases. Each line has 2 fields:

- Field 1: Alias name of device (8 chars. maximum)
- Field 2: Reference name of device as given in part 1 (8 chars. maximum)

Aliases may be used in place of actual device names when creating the *config*(CP) description file.

Part 4

This part contains the names and default values for tunable parameters. Each line has 2 or 3 fields:

- | | |
|----------|--|
| Field 1: | Parameter name to be used in the <i>config</i> (CP) description file (20 chars. maximum) |
| Field 2: | Parameter name as it will appear in the resulting <i>c.c</i> file (20 chars. maximum) |
| Field 3: | Default parameter value (20 chars. maximum) |

If a parameter has no default value, an explicit specification for the parameter must be given in the description file. See *config*(CP) for a list of the tunable parameters.

config(CP)

Name

mnttab – Format of mounted file system table.

Syntax

```
#include <stdio.h>  
#include <mnttab.h>
```

Description

The **/etc/mnttab** file contains a table of devices mounted by the **mount(C)** command.

Each table entry contains the pathname of the directory on which the device is mounted, the name of the device special file, the read/write permissions of the special file, and the date on which the device was mounted.

The maximum number of entries in **mnttab** is based on the system parameter **NMOUNT** located in **/usr/sys/conf/space.c**, which defines the number of allowable mounted special files.

See Also

mount(C)

Name

sccsfile – Format of an SCCS file.

Description

An SCCS file is an ASCII file. It consists of six logical parts: the *checksum*, the *delta table* (contains information about each delta), *user names* (contains login names and/or numerical group IDs of users who may add deltas), *flags* (contains definitions of internal keywords), *comments* (contains arbitrary descriptive information about the file), and the *body* (contains the actual text lines intermixed with control lines). Each logical part of an SCCS file is described in detail below.

Throughout an SCCS file there are lines which begin with the ASCII SOH (start of heading) character (octal 001). This character is hereafter referred to as *the control character* and will be represented graphically as @. Any line described below which is not depicted as beginning with the control character is prevented from beginning with the control character. Entries of the form DDDDD represent a five digit string (a number between 00000 and 99999).

Checksum

The checksum is the first line of an SCCS file. The form of the line is:

@hDDDDDD

The value of the checksum is the sum of all characters, except those of the first line. The @hR provides a *magic number* of (octal) 064001.

Delta Table

The delta table consists of a variable number of entries of the form:

```
@s DDDDD/DDDDDD/DDDDDD
@d <type> <SCCS ID> yr/mo/da hr:mi:se <pgmr> DDDDD DD
@i DDDDD ...
@x DDDDD ...
@g DDDDD ...
@m <MR number>
.
.
@c <comments> ...
.
.
@e
```

The first line (@s) contains the number of lines inserted/deleted/unchanged respectively. The second line (@d) contains the type of the delta (currently, normal: D, and removed: R), the SCCS ID of the delta, the date and time of creation of the delta, the login name corresponding to the real user ID at the time the delta was created, and the serial numbers of the delta and its predecessor, respectively.

The @i, @x, and @g lines contain the serial numbers of deltas included, excluded, and ignored, respectively. These lines are optional.

The @m lines (optional) each contain one MR number associated with the delta; the @c lines contain comments associated with the delta.

The @e line ends the delta table entry.

User Names

The list of login names and/or numerical group IDs of users who may add deltas to the file, separated by new-lines. The lines containing these login names and/or numerical group IDs are surrounded by the bracketing lines @u and @U. An empty list allows anyone to make a delta.

Flags

Keywords used internally (see *admin*(CP) for more information on their use). Each flag line takes the form:

```
@f <flag>      <optional text>
```

The following flags are defined:

```
@f t  <type of program>
@f v  <program name>
@f i
@f b
@f m  <module name>
@f f  <floor>
@f c  <ceiling>
@f d  <default-sid>
@f n
@f j
@f l  <lock-releases>
@f q  <user defined>
```

The t flag defines the replacement for the identification keyword. The v flag controls prompting for MR numbers in addition to

comments; if the optional text is present it defines an MR number validity checking program. The **i** flag controls the warning/error aspect of the "No id keywords" message. When the **i** flag is not present, this message is only a warning; when the **i** flag is present, this message will cause a "fatal" error (the file will not be gotten, or the delta will not be made). When the **b** flag is present the **-b** option may be used with the *get* command to cause a branch in the delta tree. The **m** flag defines the first choice for the replacement text of the *scsfile.F* identification keyword. The **f** flag defines the "floor" release; the release below which no deltas may be added. The **c** flag defines the "ceiling" release; the release above which no deltas may be added. The **d** flag defines the default SID to be used when none is specified on a *get* command. The **n** flag causes *delta* to insert a "null" delta (a delta that applies *no* changes) in those releases that are skipped when a delta is made in a *new* release (e.g., when delta 5.1 is made after delta 2.7, releases 3 and 4 are skipped). The absence of the **n** flag causes skipped releases to be completely empty. The **j** flag causes *get* to allow concurrent edits of the same base SID. The **l** flag defines a *list* of releases that are *locked* against editing (*get*(CP) with the **-e** option). The **q** flag defines the replacement for the identification keyword.

Comments

Arbitrary text surrounded by the bracketing lines @t and @T. The comments section typically contains a description of the file's purpose.

Body

The body consists of text lines and control lines. Text lines don't begin with the control character, control lines do. There are three kinds of control lines: *insert*, *delete*, and *end*, as follows:

```
@I DDDDD
@D DDDDD
@E DDDDD
```

The digit string (DDDDD) is the serial number corresponding to the delta for the control line.

XENIX Programmer's Guide

Name

stat – Data returned by stat system call.

Syntax

```
#include <sys/stat.h>
```

Description

The `sys/stat.h` include file contains the definition for the structure returned by the `stat` and `fstat` functions. The structure is defined as:

```
struct stat{
    dev_t      st_dev;      /*
                               *
                               */

    ino_t      st_ino;      /* inode number */
    ushort    sh_mode;     /* file mode */
    short      st_nlink;    /* # of links */
    ushort     st_uid;      /* owner uid */
    ushort     st_gid;      /* owner gid */
    dev_t      st_rdev;     /*
                               *
                               */

    off_t      st_size;     /* file size in bytes */
    time_t     st_atime;    /* time of last access */
    time_t     st_mtime;    /* time of last data modification */
    time_t     st_ctime;    /* time of last file status 'change' */
};
```

Note that the `st_atime`, `st_mtime`, and `st_ctime` values are measured in seconds since 00:00:00 (GMT) on January 1, 1970.

The `st_mode` value is actually a combination of one or more of the following file mode values:

```
S_IFMT      0170000 /* type of file */
S_IFDIR     0040000 /* directory */
S_IFCHR     0020000 /* character special */
S_IFBLK     0060000 /* block special */
S_IFREG     0100000 /* regular */
S_IFIFO     0010000 /* fifo */
S_IFNAM     0050000 /* name special entry */
S_INSEM     01      /* semaphore */
S_INSHD     02      /* shared memory */
S_ISUID     04000   /* set user id on execution */
S_IGUID     02000   /* set group id on execution */
S_ISVTX     01000   /* save swapped text even after use */
S_IREAD     00400   /* read permission, owner */
```

STAT (F)

STAT (F)

S_IWRITE	00200	/* write permission, owner */
S_IXEXEC	00100	/* execute/search permission, owner */

Files

stat(S)

Name

tar – archive format

Description

The command *tar*(C) dumps files to and extracts files from backup media or the hard disk.

Each file is archived in contiguous blocks, the first block being occupied by a header, whose format is given below, and the subsequent blocks of the files occupying the following blocks. All headers and file data start on 512 byte block boundaries and any spare unused space is padded with garbage. The format of a header block is as follows:

```
#define TBLOCK 512
#define NBLOCK 20
#define NAMSIZ 100
union hblock {
    char dummy[TBLOCK];
    struct header {
        char name[NAMSIZ];
        char mode[8];
        char uid[8];
        char gid[8];
        char size[12];
        char mtime[12];
        char chksum[8];
        char linkflag;
        char linkname[NAMSIZ];
        char extno[4];
        char exttotal[4];
        char efsiz[12];
    } dbuf;
} dblock;
```

The name entry is the path name of the file when archived. If the pathname starts with a zero word, the entry is empty. It is at most 100 bytes long and ends in a null byte. Mode, uid, gid, size, and time modified are the same as described under i-nodes (refer to *filesystem*(F)). The checksum entry has a value such that the sum of the words of the directory entry is zero.

If the entry corresponds to a link, then *linkname* contains the path-name of the file to which this entry is linked and *linkflag* gives a count of the links. No data is put in the archive file.

Name

term - Terminal driving tables for nroff.

Description

nroff(CT) uses driving tables to customize its output for various types of output devices, such as printing terminals, special word-processing printers (such as Diablo, Qume, or NEC Spinwriter mechanisms), or special output filter programs. These driving tables are written as C programs, compiled, and installed in */usr/lib/term/tabname*, where *name* is the name for that terminal type as shown in *term*(CT).

The structure of the tables is as follows. Sizes are in 240ths of an inch.

```
#define INCH 240
```

```
struct termtable tlp ; { \* lp is the name of the term, *\
    int bset; \* modify with new name, such as tnew *\
    int breset;
    int Hor;
    int Vert;
    int Newline;
    int Char;
    int Em;
    int Halfline;
    int Adj;
    char *twinit;
    char *twrest;
    char *twnl;
    char *hlf;
    char *hlf;
    char *flr;
    char *bdon;
    char *bdoff;
    char *iton;
    char *itoff;
    char *ploton;
    char *plotoff;
    char *up;
    char *down;
    char *right;
    char *left;
    char *codetab[256-32];
    char *zzz;
};
```

The meanings of the various fields are as follows:

<i>bset</i>	bits to set in <i>termio.c_oflag</i> see <i>tty</i> (M) and <i>termio</i> (M)). after output.
<i>breset</i>	bits to reset in <i>termio.c_oflag</i> before output.
<i>Hor</i>	horizontal resolution in fractions of an inch.
<i>Vert</i>	vertical resolution in fractions of an inch.
<i>Newline</i>	space moved by a newline (linefeed) character in fractions of an inch.
<i>Char</i>	quantum of character sizes, in fractions of an inch. (i.e., characters are multiples of Char units wide. See <i>codetab</i> below.)
<i>Em</i>	size of an em in fractions of an inch.
<i>Halfline</i>	space moved by a half-linefeed (or half-reverse-linefeed) character in fractions of an inch.
<i>Adj</i>	quantum of white space for margin adjustment in the absence of the <i>-e</i> option, in fractions of an inch. (i.e., white spaces are a multiple of Adj units wide) Note: if this is less than the size of the space character (in units of Char; see below for how the sizes of characters are defined), <i>nroff</i> will output fractional spaces using plot mode. Also, if the <i>-e</i> switch to <i>nroff</i> is used, Adj is set equal to Hor by <i>nroff</i> .
<i>twinit</i>	set of characters used to initialize the terminal in a mode suitable for <i>nroff</i> .
<i>twrest</i>	set of characters used to restore the terminal to normal mode.
<i>twnl</i>	set of characters used to move down one line.
<i>hlr</i>	set of characters used to move up one-half line.
<i>hlf</i>	set of characters used to move down one-half line.
<i>flr</i>	set of characters used to move up one line.
<i>bdon</i>	set of characters used to turn on hardware boldface mode, if any. <i>Nroff</i> assumes that boldface mode is reset automatically by the <i>twnl</i> string, because many letter-quality printers reset the boldface mode when they receive a carriage return; the <i>twnl</i> string should include

	whatever characters are necessary to reset the boldface mode.
<i>bdoff</i>	set of characters used to turn off hardware boldface mode, if any.
<i>iton</i>	set of characters used to turn on hardware italics mode, if any.
<i>itoff</i>	set of characters used to turn off hardware italics mode, if any.
<i>ploton</i>	set of characters used to turn on hardware plot mode (for Diablo-type mechanisms), if any.
<i>plotoff</i>	set of characters used to turn off hardware plot mode (for Diablo-type mechanisms), if any.
<i>up</i>	set of characters used to move up one resolution unit (Vert) in plot mode, if any.
<i>down</i>	set of characters used to move down one resolution unit (Vert) in plot mode, if any.
<i>right</i>	set of characters used to move right one resolution unit (Hor) in plot mode, if any.
<i>left</i>	set of characters used to move left one resolution unit (Hor) in plot mode, if any.
<i>codetab</i>	Array of sequences to print individual characters. Order is <i>nroff</i> 's internal ordering. See the file <code>/usr/lib/term/tabuser.c</code> for the exact order.
<i>zzz</i>	a zero terminator at the end.

The *codetab* sequences each begin with a flag byte. The top bit indicates whether the sequence should be underlined in the `.ul` font. The rest of the byte is the width of the sequence in units of *Char*.

The remainder of each *codetab* sequence is a sequence of characters to be output. Characters with the top bit off are output as given; characters with the top bit on indicate escape into plot mode. When such an escape character is encountered, *nroff* shifts into plot mode, emitting *ploton*, and skips to the next character if the escape character was `^200`.

When in plot mode, characters with the top bit off are output as given. A character with the top bit on indicates a motion. The next bit indicates coordinate, with **1** being vertical and **0** being horizontal. The next bit indicates direction, with **1** meaning up or left.

The remaining five bits give the amount of the motion. An amount of zero causes exit from plot mode.

When plot mode is exited, either at the end of the string or via the amount-zero exit, *plottoff* is emitted followed by a blank.

All quantities which are in units of fractions of an inch should be expressed as `INCH*num/denom`, where *num* and *denom* are respectively the numerator and denominator of the fraction; that is, 1/48 of an inch would be written as "INCH/48".

If any sequence of characters does not pertain to the output device, that sequence should be given as a null string.

The XENIX Development System must be installed on the computer to create a new driving table. The source code for a generic output device is in the file `/usr/lib/term/tabuser.c`. Copy this file and make the necessary modifications, including the name of the `termtable` struct. Refer to the hardware manual for the codes needed for the output device (terminal, printer, etc.). Name the file according to the convention explained in *term*(CT). The makefile, `/usr/lib/term/makefile`, should be updated to include the source file to the new driving table. When the files are prepared, enter the command :

```
make cp
```

(See *make*(CP)). The source to the new driving table is linked with the object file *mkterm.o*, and the new driving table is created and installed in the proper directory.

FILES

```
/usr/lib/term/tabname  driving tables
/usr/lib/term/tabuser.c generic source for driving tables
/usr/lib/term/makefile  makefile for creating driving tables
/usr/lib/term/mkterms.o linkable object file for creating driving tables
```

SEE ALSO

nroff(CT), *term*(CT).

TERM (F)

TERM (F)

Notes

The XENIX Development System must be installed on the computer to create new driving tables.

Not all XENIX facilities support all of these options.

Name

types – Primitive system data types.

Syntax

```
#include <sys/types.h>
```

Description

The data types defined in the include file `<sys/types.h>` are used in XENIX system code; some data of these types are accessible to user code.

The form *daddr_t* is used for disk addresses except in an inode on disk, see *filesystem(F)*. Times are encoded in seconds since 00:00:00 GMT, January 1, 1970. The major and minor parts of a device code specify kind and unit number of a device and are installation-dependent. Offsets are measured in bytes from the beginning of a file. The *label_t* variables are used to save the processor state while another process is running.

filesystem(F)

Name

varargs - variable argument list

Synopsis

```
#include <varargs.h>

function(va_alist)
va_dcl
va_list pvar;
va_start(pvar);
f = va_arg(pvar, type);
va_end(pvar);
```

Description

This set of macros provides a means of writing portable procedures that accept variable argument lists. Routines having variable argument lists (such as *printf(S)*) that do not use varargs are inherently nonportable, since different machines use different argument passing conventions.

va_alist is used in a function header to denote a variable argument list.

va_dcl is a declaration for *va_alist*. Note that there is no semicolon after *va_dcl*.

va_list is a type which can be used for the variable *pvar*, which is used to traverse the list. One such variable must always be declared.

va_start(pvar) is called to initialize *pvar* to the beginning of the list.

va_arg(pvar, type) will return the next argument in the list pointed to by *pvar*. *type* is the type the argument is expected to be. Different types can be mixed but it is up to the routine to know what type of argument is expected since it cannot be determined at run-time.

va_end(pvar) is used to finish up.

Multiple traversals, each bracketed by *va_start* ... *va_end*, are possible.

Example

```

#include <stdio.h>
#include <varargs.h>

main()
{
    show(2, 3.1, "but", 4.1, "end");
    show(1, 5.9, "hello");
    show(4, 6.2, "oops", 5.3, "blah", 5.1, "lovely", 2.3, "madrigal");
}

/*
 * the first argument is an int which tells how many pairs follow.
 * the pairs are doubles and character pointers
 *
 * remember that when variables are passed to functions
 * floats are promoted to doubles and chars to ints.
 */
show(n, va_alist)
int n;
va_dcl
{
    va_list ap;
    int i;
    double f;
    char *p;

    va_start(ap);
    for (i = 0; i < n; ++i) {
        f = va_arg(ap, double);
        p = va_arg(ap, char *);
        printf("%4.1f %s\n", f, p);
    }
    va_end(ap);
}

```

Bugs

It is up to the calling routine to determine how many arguments there are, since it is not possible to determine this from the stack frame. For example, *excel* passes a 0 to signal the end of the list. *Printf* can tell how many arguments are supposed to be there by the format.

Permuted Index

Commands, System Calls, Library Routines and File Formats

This permuted index is derived from the "Name" description lines found on each reference manual page. Each *index* line shows the title of the entry to which the line refers, followed by the reference manual section letter where the page is found.

To use the *permuted index* search the middle column for a key word or phrase. The right hand column contains the name and section letter of the manual page that documents the key word or phrase. The left column contains additional useful information about the command. Commands or routines are also listed in the context of the *index* line, followed by a colon (:). This denotes the "beginning" of the sentence. Notice that in many cases, the lines wrap, starting in the middle column and ending in the left column. A slash (/) indicates that the description line is truncated.

 Terminal capability data base. termcap: termcap(M)
 names from pathnames. basename: Removes directory . . . basename(C)
 later time. at, batch: Executes commands at a . . . at(C)
 bc: Invokes a calculator. bc(C)
 for diff. bdiff: Compares files too large . . . bdiff(C)
 bdos: Invokes a DOS system call. bdos(DOS)
 cb: Beautifies C programs. cb(CP)
 j0, j1, jn, y0, y1, yn: Performs Bessel functions. bessel(S)
 Performs Bessel functions. bessel, j0, j1, jn, y0, y1, yn: . . . bessel(S)
 bfs: Scans big files. bfs(C)
 fixhdr: Changes executable binary file headers. fixhdr(C)
 fread, fwrite: Performs buffered binary input and output. . . . fread(S)
 bsearch: Performs a binary search. bsearch(S)
 tfind, tdelete, twalk: Manages binary search trees. tsearch, . . . tsearch(S)
 Creates an instance of a binary semaphore. creatsem: . . . creatsem(S)
 Removes symbols and relocation bits. strip: strip(CP)
 shutdn: Flushes block I/O and halts the CPU. shutdn(S)
 cmchk: Reports hard disk block size. cmchk(C)
 df: Report number of free disk blocks. df(C)
 Calculates checksum and counts blocks in a file. sum: sum(C)

boot: XENIX	boot program.	boot(HW)
	boot: XENIX boot program.	boot(HW)
autoboot: Automatically	boots the system.	autoboot(M)
allocation. sbrk,	brk: Changes data segment space	sbrk(S)
segment.	brkctl: Allocates data in a far	brkctl(S)
search.	bsearch: Performs a binary	bsearch(S)
a character to the console	buffer. ungetch: Returns	ungetch(DOS)
output. fread, fwrite: Performs	buffered binary input and	fread(S)
stdio: Performs standard	buffered input and output.	stdio(S)
setbuf, setvbuf: Assigns	buffering to a stream.	setbuf(S)
flushall: Flushes all output	buffers.	flushall(DOS)
	mknod: Builds special files.	mknod(C)
	inp: Returns a byte.	inp(DOS)
	outp: Writes a byte to an output port.	outp(DOS)
movedata: Copies	bytes from a specific address.	movedata(DOS)
	swab: Swaps bytes.	swab(S)
cc: Invokes the	C Compiler.	cc(CP)
cflow: Generates	C flow graph.	cflow(CP)
	cpp: The C language preprocessor.	cpp(CP)
lint: Checks	C language usage and syntax.	lint(CP)
cxref: Generates	C program cross-reference.	cxref(CP)
cb: Beautifies	C programs.	cb(CP)
stack requirements for	C programs. /Determines	stackuse(CP)
xref: Cross-references	C programs.	xref(CP)
xstr: Extracts strings from	C programs.	xstr(CP)
an error message file from	C source. mkstr: Creates	mkstr(CP)
distance. hypot,	cabs: Determines Euclidean	hypot(S)
	cal: Prints a calendar.	cal(C)
blocks in a file. sum:	Calculates checksum and counts	sum(C)
bc: Invokes a	calculator.	bc(C)
Invokes an arbitrary precision	calculator. dc:	dc(C)
	cal: Prints a calendar.	cal(C)
service.	calendar: Invokes a reminder	calendar(C)
bdos: Invokes a DOS system	call.	bdos(DOS)
intdos: Invokes a DOS system	call.	intdos(DOS)
intdosx: Invokes a DOS system	call.	intdosx(DOS)
Data returned by stat system	call. stat:	stat(F)
exit: Terminates the	calling process.	exit(DOS)
malloc, free, realloc,	calloc: Allocates main memory.	malloc(S)
	cu: Calls another XENIX system.	cu(C)
lineprinter. lp, lpr,	cancel: Send/cancel requests to	lp(C)
termcap: Terminal	capability data base.	termcap(M)
	files. cat: Concatenates and displays	cat(C)
	cb: Beautifies C programs.	cb(CP)
	cc: Invokes the C Compiler.	cc(CP)
	cd: Changes working directory.	cd(C)
commentary of an SCCS delta.	cdc: Changes the delta	cdc(CP)
value, floor,/ floor, fabs,	ceil, fmod: Performs absolute	floor(S)
/Performs absolute value, floor,	ceiling and remainder functions.	floor(S)
	cflow: Generates C flow graph.	cflow(CP)
	(change) to an SCCS file.	delta(CP)
delta: Makes a delta	clockrate: Changes clock rate.	clockrate(C)
allocation. sbrk, brk:	Changes data segment space	sbrk(S)
headers. fixhdr:	Changes executable binary file	fixhdr(C)
chgrp:	Changes group ID.	chgrp(C)

passwd: Changes login password. passwd(C)
 chmod: Changes mode of a file. chmod(S)
 environment. putenv: Changes or adds value to putenv(S)
 chown: Changes owner ID. chown(C)
 nice: Changes priority of a process. nice(S)
 command. chroot: Changes root directory for chroot(C)
 modification dates of/ settime: Changes the access and settime(C)
 of a file or directory. chmod: Changes the access permissions chmod(C)
 an SCCS delta. cdc: Changes the delta commentary of cdc(CP)
 file. newform: Changes the format of a text newform(C)
 file. chown: Changes the owner and group of a chown(S)
 chroot: Changes the root directory. chroot(S)
 chsize: Changes the size of a file. chsize(S)
 chdir: Changes the working directory. chdir(S)
 cd: Changes working directory. cd(C)
 stream. ungetc: Pushes character back into input ungetc(S)
 isatty: Checks for a character device. isatty(DOS)
 ioctl: Controls character devices. ioctl(S)
 fgetc, fgetchar: Gets a character from a stream. fgetc(DOS)
 getch: Gets a character. getch(DOS)
 getche: Gets and echoes a character. getche(DOS)
 getc, getchar, fgetc, getw: Gets character or word from a stream. getc(S)
 /putchar, fputc, putw: Puts a character or word on a stream. putc(S)
 ascii: Map of the ASCII character set. ascii(M)
 fputc, fputchar: Write a character to a stream. fputc(DOS)
 ungetch: Returns a character to the console buffer. ungetch(DOS)
 putch: Writes a character to the console. putch(DOS)
 style: Analyzes characteristics of a document. style(CT)
 tolower, toascii: Translates characters. conv, toupper, conv(S)
 iscntrl, isascii: Classifies characters. /isprint, isgraph, ctype(S)
 strrev: Reverses the order of characters in a string. strrev(DOS)
 charater. strset: Sets all characters in a string to one strset(DOS)
 ltoa: Converts long integers to characters. ltoa(DOS)
 strtolwr: Converts uppercase characters to lowercase. strtolwr(DOS)
 strupr: Converts lowercase characters to uppercase. strupr(DOS)
 tr: Translates characters. tr(C)
 ultoa: Converts numbers to characters. ultoa(DOS)
 wc: Counts lines, words and characters. wc(C)
 characters in a string to one charater. strset: Sets all strset(DOS)
 directory. chdir: Changes the working chdir(S)
 constant-width text for/ cw, checkcw, cwcheck: Prepares cw(CT)
 mathematical text/ eqn, neqn, checkeq, eqncheck: Formats eqn(CT)
 processed by fsck. checklist: List of file systems checklist(F)
 of MM macros. checkmm, mmcheck: Checks usage checkmm(CT)
 waitsem, nbwaitsem: Awaits and checks access to a resource/ waitsem(S)
 fsck: Checks and repairs file systems. fsck(C)
 syntax. lint: Checks C language usage and lint(CP)
 isatty: Checks for a character device. isatty(DOS)
 grpcheck: Checks group file. grpcheck(C)
 diction: Checks language usage. diction(CT)
 pwcheck: Checks password file. pwcheck(C)
 keystroke. kbhit: Checks the console for a kbhit(DOS)
 to be read. rdchk: Checks to see if there is data rdchk(S)
 checkmm, mmcheck: Checks usage of MM macros. checkmm(CT)
 file. sum: Calculates checksum and counts blocks in a sum(C)

	chgrp: Changes group ID.	chgrp(C)
times: Gets process and	child process times.	times(S)
terminate. wait: Waits for a	child process to stop or	wait(S)
	chmod: Changes mode of a file. . . .	chmod(S)
permissions of a file or/	chmod: Changes the access	chmod(C)
	chown: Changes owner ID.	chown(C)
group of a file.	chown: Changes the owner and	chown(S)
for command.	chroot: Changes root directory	chroot(C)
directory.	chroot: Changes the root	chroot(S)
file.	chsize: Changes the size of a	chsize(S)
isgraph, iscntrl, isascii:	Classifies characters. /isprint,	ctype(S)
directory. uuclean:	Clean-up the uucp spool	uuclean(C)
stream status. ferrord, feof,	clearerr, fileno: Determines	ferrord(S)
	clri: Clears inode.	clri(C)
a shell command interpreter with	C-like syntax. csh: Invokes	csh(C)
alarm: Sets a process' alarm	clock.	alarm(S)
system real-time (time of day)	clock. clock: The	clock(M)
clockrate: Changes	clock rate.	clockrate(C)
	clock: Reports CPU time used.	clock(S)
system real-time (time of day)	clock. setclock: Sets the	setclock(M)
(time of day) clock.	clock: The system real-time	clock(M)
	clockrate: Changes clock rate.	clockrate(C)
operations.	closedir: Performs directory	directory(S)
close:	Closes a file descriptor.	close(S)
fclose, fflush:	Closes or flushes a stream.	fclose(S)
halts the CPU. haltsys:	Closes out the file systems and	haltsys(C)
fclose, fcloseall:	Closes streams.	fclose(DOS)
	clri: Clears inode.	clri(C)
size.	cmchk: Reports hard disk block	cmchk(C)
configuration data base.	Cmos: Displays and sets the	cmos(HW)
	cmp: Compares two files.	cmp(C)
	col: Filters reverse linefeeds.	col(CT)
setcolor: Set screen	color.	setcolor(C)
lc: Lists directory contents in	columns.	lc(C)
	comb: Combines SCCS deltas.	comb(CP)
comb:	Combines SCCS deltas.	comb(CP)
common to two sorted files.	comm: Selects or rejects lines	comm(C)
nice: Runs a	command at a different priority. . . .	nice(C)
Changes root directory for	command. chroot:	chroot(C)
segread:	command description.	segread(DOS)
env: Sets environment for	command execution.	env(C)
quits. nohup: Runs a	command immune to hangups and	nohup(C)
rsh: Invokes a restricted shell	(command interpreter).	rsh(C)
sh: Invokes the shell	command interpreter.	sh(C)
shV: Invokes the shell	command interpreter.	shV(C)
syntax. csh: Invokes a shell	command interpreter with C-like	csh(C)
uux: Executes	command on remote XENIX.	uux(C)
getopt: Parses	command options.	getopt(C)
system: Executes a shell	command.	system(S)
time: Times a	command.	time(CP)
at, batch: Executes	commands at a later time.	at(C)
cron: Executes	commands at specified times.	cron(C)
micnet: The Micnet default	commands file.	micnet(M)
help: Asks for help about SCCS	commands.	help(CP)
intro: Introduces XENIX	commands.	Intro(C)

XENIX Development System	commands. intro: Introduces . . .	Intro(CP)
Introduces text processing	commands. intro:	Intro(CT)
system. remote: Executes	commands on a remote XENIX . . .	remote(C)
xargs: Constructs and executes	commands.	xargs(C)
cdc: Changes the delta	commentary of an SCCS delta. . . .	cdc(CP)
comm: Selects or rejects lines	common to two sorted files.	comm(C)
/the status of inter-process	communication facilities.	ipcs(C)
ftok: Standard interprocess	communication package.	stdipc(S)
dircmp:	Compares directories.	dircmp(C)
sdiff:	Compares files side-by-side.	sdiff(C)
diff. bdiff:	Compares files too large for	bdiff(C)
diskcp, diskcmp: Copies or	compares floppy disks.	diskcp(C)
diff3:	Compares three files.	diff3(C)
cmp:	Compares two files.	cmp(C)
diff:	Compares two text files.	diff(C)
file. sccsdiff:	Compares two versions of an SCCS .	sccsdiff(CP)
regexp: Regular expression	compile and match routines.	regexp(S)
cc: Invokes the C	Compiler.	cc(CP)
yacc: Invokes a	compiler-compiler.	yacc(CP)
expressions. regex, regcmp:	Compiles and executes regular . . .	regex(S)
regcmp:	Compiles regular expressions. . . .	regcmp(CP)
erf, erfc: Error function and	complementary error function. . . .	erf(S)
processes. wait: Awaits	completion of background	wait(C)
pack, pcat, unpack:	Compresses and expands files. . . .	pack(C)
console, tty[02-n] -	Computer screen.	console(HW)
cat:	Concatenates and displays files. . .	cat(C)
test: Tests	conditions.	test(C)
system. config:	Configures a XENIX	config(CP)
Cmos: Displays and sets the	configuration data base.	cmos(HW)
mapkey, mapscrn, mapstr:	Configure console screen/	mapkey(M)
config:	Configures a XENIX system.	config(CP)
spooling system. lpadmin:	Configures the lineprinter	lpadmin(C)
an out-going terminal line	connection. dial: Establishes	dial(S)
Returns a character to the	console buffer. ungetch:	ungetch(DOS)
cputs: Puts a string to the	console.	cputs(DOS)
kbhit: Checks the	console for a keystroke.	kbhit(DOS)
cscanf: Converts and formats	console input.	cscanf(DOS)
keyboard: The	console keyboard.	keyboard(HW)
messages: Description of system	console messages.	messages(M)
putch: Writes a character to the	console.	putch(DOS)
mapscrn, mapstr: Configure	console screen mapping. mapkey, . .	mapkey(M)
Computer screen.	console, tty[02-n] -	console(HW)
cw, checkcw, cwcheck: Prepares	constant-width text for troff.	cw(CT)
mkfs:	Constructs a file system.	mkfs(C)
commands. xargs:	Constructs and executes	xargs(C)
nroff/troff, tbl, and eqn	constructs. deroff: Removes	deroff(CT)
lc: Lists directory	contents in columns.	lc(C)
ls: Gives information about	contents of directories.	ls(C)
l: Lists information about	contents of directory.	l(C)
Splits files according to	context. csplit:	csplit(C)
uinstall: Administer UUCP	control files.	uinstall(C)
init: Process	control initialization.	init(M)
msgctl: Provides message	control operations.	msgctl(S)
uucp status inquiry and job	control. uustat:	uustat(C)
ioctl:	Controls character devices.	ioctl(S)

fcntl: Controls open files. fcntl(S)
 semctl: Controls semaphore operations. semctl(S)
 operations. shmctl: Controls shared memory shmctl(S)
 Translates characters. conv, toupper, tolower, toascii: . . . conv(S)
 term: Conventional names. term(CT)
 fcvt, gcvt: Performs output conversions. ecvt, ecvt(S)
 double-precision/ strtod: Converts a string to a strtod(S)
 dd: Converts and copies a file. dd(C)
 input. cscanf: Converts and formats console cscanf(DOS)
 scanf, fscanf, sscanf: Converts and formats input. scanf(S)
 libraries. randlib: Converts archives to random randlib(CP)
 atof, atoi, atol: Converts ASCII to numbers. atof(S)
 and long/ l3tol, ltol3: Converts between 3-byte integers . . . l3tol(S)
 and base 64 ASCII. a64l, l64a: Converts between long integer . . . a64l(S)
 /gmtime, asctime, tzset: Converts date and time to ASCII. . . . ctime(S)
 characters. ltoa: Converts long integers to ltoa(DOS)
 uppercase. strupr: Converts lowercase characters to . . . strupr(DOS)
 ultoa: Converts numbers to characters. ultoa(DOS)
 itoa: Converts numbers to integers. itoa(DOS)
 standard FORTRAN. ratfor: Converts Rational FORTRAN into . . . ratfor(CP)
 strtol, atol, atoi: Converts string to integer. strtol(S)
 units: Converts units. units(C)
 lowercase. strtolwr: Converts uppercase characters to . . . strtolwr(DOS)
 dd: Converts and copies a file. dd(C)
 address. movedata: Copies bytes from a specific movedata(DOS)
 cpio: Copies file archives in and out. cpio(C)
 systems. rcp: Copies files across XENIX rcp(C)
 cp: Copies files. cp(C)
 copy: Copies groups of files. copy(C)
 diskcp, diskcmp: Copies or compares floppy disks. diskcp(C)
 copy: Copies groups of files. copy(C)
 Public XENIX-to-XENIX file copy. uuto, uupick: uuto(C)
 core: Format of core image file. core(F)
 core: Format of core image file. core(F)
 asktime: Prompts for the correct time of day. asktime(C)
 explain: Corrects language usage. explain(CT)
 atan2: Performs/ sin, cos, tan, asin, acos, atan, trig(S)
 functions. sinh, cosh, tanh: Performs hyperbolic sinh(S)
 sum: Calculates checksum and counts blocks in a file. sum(C)
 characters. wc: Counts lines, words and wc(C)
 cp: Copies files. cp(C)
 cpio: Format of cpio archive. cpio(F)
 and out. cpio: Copies file archives in cpio(C)
 cpio: Format of cpio archive. cpio(F)
 preprocessor. cpp: The C language cpp(CP)
 cprintf: Formats output. cprintf(DOS)
 the file systems and halts the CPU. haltsys: Closes out haltsys(C)
 Flushes block I/O and halts the CPU. shutdown: shutdown(S)
 clock: Reports CPU time used. clock(S)
 console. cputs: Puts a string to the cputs(DOS)
 rewrites an existing one. creat: Creates a new file or creat(S)
 file. tmpnam, tempnam: Creates a name for a temporary tmpnam(S)
 mkdir: Creates a new directory. mkdir(DOS)
 an existing one. creat: Creates a new file or rewrites creat(S)
 fork: Creates a new process. fork(S)

spawnl, spawnvp: Creates a new process. spawn(DOS)
 ctags: Creates a tags file. ctags(CP)
 tee: Creates a tee in a pipe. tee(C)
 tmpfile: Creates a temporary file. tmpfile(S)
 from C source. mkstr: Creates an error message file mkstr(CP)
 profile. profil: Creates an execution time profil(S)
 semaphore. creatsem: Creates an instance of a binary creatsem(S)
 pipe: Creates an interprocess pipe. pipe(S)
 files. admin: Creates and administers SCCS admin(CP)
 /fixed disk for flaws and creates flaw map. badtrk(M)
 umask: Sets and gets file creation mask. umask(S)
 a binary semaphore. creatsem: Creates an instance of creatsem(S)
 listing. cref: Makes a cross-reference cref(CP)
 specified times. cron: Executes commands at cron(C)
 intro: Introduction to DOS cross development functions. . . . intro(DOS)
 dosld: XENIX to MS-DOS cross linker. dosld(CP)
 cxref: Generates C program cross-reference. cxref(CP)
 cref: Makes a cross-reference listing. cref(CP)
 xref: Cross-references C programs. xref(CP)
 console input. cscanf: Converts and formats cscanf(DOS)
 interpreter with C-like syntax. csh: Invokes a shell command csh(C)
 to context. csplit: Splits files according csplit(C)
 ctags: Creates a tags file. ctags(CP)
 ctermid: Generates a filename ctermid(S)
 asctime, tzset: Converts date/ ctime, localtime, gmtime, ctime(S)
 islower, isdigit, isxdigit, ctype, isalpha, isupper, ctype(S)
 cu: Calls another XENIX system. cu(C)
 pointer. tell: Gets the current position of the file tell(DOS)
 activity. sact: Prints current SCCS file editing sact(CP)
 the slot in the utmp file of the current user. ttyslot: Finds ttyslot(S)
 getcwd: Get the pathname of current working directory. getcwd(S)
 uname: Prints the name of the current XENIX system. uname(C)
 uname: Gets name of current XENIX system. uname(S)
 cursor functions. curses: Performs screen and curses(S)
 curses: Performs screen and cursor functions. curses(S)
 spline: Interpolates smooth curve. spline(CP)
 the user. cuserid: Gets the login name of cuserid(S)
 each line of a file. cut: Cuts out selected fields of cut(CT)
 line of a file. cut: Cuts out selected fields of each cut(CT)
 constant-width text for troff. cw, checkcw, cwcheck: Prepares cw(CT)
 text for troff. cw, checkcw, cwcheck: Prepares constant-width cw(CT)
 cross-reference. cxref: Generates C program cxref(CP)
 daemon.mn: Micnet mailer daemon. daemon.mn(M)
 daemon.mn: Micnet mailer daemon. daemon.mn(M)
 sdwaitv: Synchronizes shared data access. sdgetv, sdgetv(S)
 and sets the configuration data base. Cmos: Displays cmos(HW)
 termcap: Terminal capability data base. termcap(M)
 brkctl: Allocates data in a far segment. brkctl(S)
 /sgetl: Accesses long integer data in a machine-independent. . . . sputl(S)
 plock: Lock process, text, or data in memory. plock(S)
 prof: Displays profile data. prof(CP)
 call. stat: Data returned by stat system stat(F)
 Synchronizes access to a shared data segment. sdenter, sdleave: . . . sdenter(S)
 Attaches and detaches a shared data segment. sdget, sdfree: sdget(S)
 sbrk, brk: Changes data segment space allocation. . . . sbrk(S)

rdchk: Checks to see if there is	data to be read.	rdchk(S)
types: Primitive system	data types.	types(F)
firstkey, nextkey: Performs	database functions. /delete,	dbm(S)
/gmtime, asctime, tzset: Converts	date and time to ASCII.	ctime(S)
date: Prints and sets the	date.	date(C)
	date: Prints and sets the date. . . .	date(C)
time, ftime: Gets time and	date.	time(S)
the access and modification	dates of files. /Changes	settime(C)
sddate: Prints and sets backup	dates.	sddate(C)
Prompts for the correct time of	day, asktime:	asktime(C)
The system real-time (time of	day) clock. clock:	clock(M)
the system real-time (time of	day) clock. setclock: Sets	setclock(M)
firstkey, nextkey: Performs/	dbminit, fetch, store, delete,	dbm(S)
precision calculator.	dc: Invokes an arbitrary	dc(C)
	dd: Converts and copies a file. . . .	dd(C)
devices. assign,	deassign: Assigns and deassigns . .	assign(C)
assign, deassign: Assigns and	deassigns devices.	assign(C)
adb: Invokes a general-purpose	debugger.	adb(CP)
micnet: The Micnet	default commands file.	micnet(M)
information directory.	default: Default program	default(M)
defopen, defread: Reads	default entries.	defopen(S)
directory.	Default program information	default(M)
	entries. defopen, defread: Reads default .	defopen(S)
	defopen, defread: Reads default entries. . .	defopen(S)
Performs/ dbminit, fetch, store,	delete, firstkey, nextkey:	dbm(S)
rmdir:	Deletes a directory.	rmdir(DOS)
pathname. dirname:	Delivers directory part of	dirname(C)
file. tail:	Delivers the last part of a	tail(C)
the delta commentary of an SCCS	delta. cdc: Changes	cdc(CP)
delta: Makes a	delta (change) to an SCCS file. . . .	delta(CP)
delta. cdc: Changes the	delta commentary of an SCCS	cdc(CP)
rmdel: Removes a	delta from an SCCS file.	rmdel(CP)
an SCCS file.	delta: Makes a delta (change) to . .	delta(CP)
comb: Combines SCCS	deltas.	comb(CP)
terminal. msg: Permits or	denies messages sent to a	msg(C)
tbl, and eqn constructs.	deroff: Removes nroff/troff,	deroff(CT)
Machine:	Description of host machine.	machine(HW)
messages. messages:	Description of system console	messages(M)
segread: command	description.	segread(DOS)
close: Closes a file	descriptor.	close(S)
dup2: Duplicates an open file	descriptor. dup,	dup(S)
sdget, sdfree: Attaches and	detaches a shared data segment. . .	sdget(S)
file. access:	Determines accessibility of a	access(S)
dtype:	Determines disk type.	dtype(C)
eof:	Determines end-of-file,	eof(DOS)
hypot, cabs:	Determines Euclidean distance. . .	hypot(S)
file:	Determines file type.	file(C)
for C programs. stackuse:	Determines stack requirements . .	stackuse(CP)
error, feof, clearerr, fileno:	Determines stream status.	error(S)
whodo:	Determines who is doing what. . . .	whodo(C)
master: Master	device information table.	master(F)
lp, lp0, lp1, lp2: Line printer	device interfaces.	lp(HW)
isatty: Checks for a character	device.	isatty(DOS)
devnm: Identifies	device name.	devnm(C)
deassign: Assigns and deassigns	devices. assign,	assign(C)

ioctl: Controls character devices.	ioctl(S)
devnm: Identifies device name. . . .	devnm(C)
blocks. df: Report number of free disk	df(C)
dial: Dials a modem.	dial(M)
terminal line connection. dial: Establishes an out-going	dial(S)
dial: Dials a modem.	dial(M)
diction: Checks language usage. . . .	diction(CT)
diff: Compares two text files.	diff(C)
diff3: Compares three files.	diff3(C)
diffmk: Marks differences between files.	diffmk(CT)
between files. diffmk: Marks differences	diffmk(CT)
dir: Format of a directory.	dir(F)
dircmp: Compares directories.	dircmp(C)
dircmp: Compares directories.	dircmp(C)
information about contents of directories. ls: Gives	ls(C)
mv: Moves or renames files and directories.	mv(C)
rm, rmdir: Removes files or directories.	rm(C)
rmdir: Removes directories.	rmdir(C)
cd: Changes working directory.	cd(C)
chdir: Changes the working directory.	chdir(S)
access permissions of a file or directory. chmod: Changes the	chmod(C)
chroot: Changes the root directory.	chroot(S)
lc: Lists directory contents in columns. . . .	lc(C)
Default program information directory. default:	default(M)
dir: Format of a directory.	dir(F)
unlink: Removes directory entry.	unlink(S)
chroot: Changes root directory for command.	chroot(C)
the pathname of current working directory. getcwd: Get	getcwd(S)
information about contents of directory. l: Lists	l(C)
mkdir: Makes a directory.	mkdir(C)
mkdir: Creates a new directory.	mkdir(DOS)
mvd: Moves a directory.	mvd(C)
pwd: Prints working directory name.	pwd(C)
basename: Removes directory names from pathnames. . . .	basename(C)
closedir: Performs directory operations.	directory(S)
ordinary file. mknod: Makes a directory, or a special or	mknod(S)
dirname: Delivers directory part of pathname.	dirname(C)
rename: renames a file or directory.	rename(DOS)
rmdir: Deletes a directory.	rmdir(DOS)
uuclean: Clean-up the uucp spool directory.	uuclean(C)
of pathname. dirname: Delivers directory part	dirname(C)
printers. disable: Turns off terminals and	disable(C)
acct: Enables or disables process accounting. . . .	acct(S)
type, modes, speed, and line discipline. /Sets terminal	getty(M)
cmchk: Reports hard disk block size.	cmchk(C)
df: Report number of free disk blocks.	df(C)
hd: Internal fixed disk drive.	hd(HW)
map. badtrk - Scans fixed disk for flaws and creates flaw	badtrk(M)
fdisk: Maintain disk partitions.	fdisk(C)
dtype: Determines disk type.	dtype(C)
du: Summarizes disk usage.	du(C)
floppy disks. diskcp, diskcmp: Copies or compares	diskcp(C)
compares floppy disks. diskcp, diskcmp: Copies or	diskcp(C)
Copies or compares floppy disks. diskcp, diskcmp:	diskcp(C)
umount: Dismounts a file structure.	umount(C)

vi: Invokes a screen-oriented	display editor.	vedit(C)
vi: Invokes a screen-oriented	display editor.	vi(C)
vi: Invokes a screen-oriented	display editor.	view(C)
configuration data base. Cmos:	Displays and sets the	cmos(HW)
cat: Concatenates and	displays files.	cat(C)
format. hd:	Displays files in hexadecimal	hd(C)
od:	Displays files in octal format.	od(C)
prof:	Displays profile data.	prof(CP)
object files. hdr:	Displays selected parts of	hdr(CP)
mail: Sends, reads or	disposes of mail.	mail(C)
cabs: Determines Euclidean	distance. hypot,	hypot(S)
lcong48: Generates uniformly	distributed. srand48, seed48,	drand48(S)
	divvy -b block_device -c c/	divvy(C)
Analyzes characteristics of a	document. style:	style(CT)
mm macros. mm: Prints	documents formatted with the	mm(CT)
mmt: Typesets	documents.	mmt(CT)
whodo: Determines who is	doing what.	whodo(C)
	dos: Accesses DOS files.	dos(C)
	dos: Accesses DOS files.	doscat(C)
	dos: Accesses DOS files.	doscp(C)
	dos: Accesses DOS files.	dosdir(C)
	dos: Accesses DOS files.	dosls(C)
	dos: Accesses DOS files.	dosrm(C)
	dos: Accesses DOS files.	dosrmdir(C)
intro: Introduction to	DOS cross development functions. . .	intro(DOS)
dosexterr: Gets	DOS error messages.	dosexter(DOS)
dos: Accesses	DOS files.	dos(C)
dos: Accesses	DOS files.	doscat(C)
dos: Accesses	DOS files.	doscp(C)
dos: Accesses	DOS files.	dosdir(C)
dos: Accesses	DOS files.	dosls(C)
dos: Accesses	DOS files.	dosrm(C)
dos: Accesses	DOS files.	dosrmdir(C)
bdos: Invokes a	DOS system call.	bdos(DOS)
intdos: Invokes a	DOS system call.	intdos(DOS)
intdosx: Invokes a	DOS system call.	intdosx(DOS)
messages.	dosexterr: Gets DOS error	dosexter(DOS)
linker.	dosld: XENIX to MS-DOS cross . . .	dosld(CP)
/atof: Converts a string to a	double-precision number.	strtod(S)
hd: Internal fixed disk	drive.	hd(HW)
term: Terminal	driving tables for nroff.	term(F)
	dtype: Determines disk type.	dtype(C)
	du: Summarizes disk usage.	du(C)
format.	dump: Incremental dump tape	dump(F)
system backup.	dump: Performs incremental file . .	dump(C)
backup: Incremental	dump tape format.	backup(F)
dump: Incremental	dump tape format.	dump(F)
files on a backup archive.	dumpdir: Prints the names of	dumpdir(C)
file descriptor.	dup, dup2: Duplicates an open	dup(S)
descriptor. dup,	dup2: Duplicates an open file	dup(S)
descriptor. dup, dup2:	Duplicates an open file	dup(S)
	echo: Echoes arguments.	echo(C)
getche: Gets and	echoes a character.	getche(DOS)
echo:	Echoes arguments.	echo(C)
output conversions.	ecvt, fcvt, gcvt: Performs	ecvt(S)

ed: Invokes the text editor. ed(C)
 program. end, etext, edata: Last locations in end(S)
 sact: Prints current SCCS file editing activity. sact(CP)
 ed: Invokes the text editor. ed(C)
 ex: Invokes a text editor. ex(C)
 ld: Invokes the link editor. ld(CP)
 ld: Invokes the link editor. ld(M)
 Format of assembler and link editor output. a.out: a.out(F)
 sed: Invokes the stream editor. sed(C)
 a screen-oriented display editor. vi: Invokes vedit(C)
 a screen-oriented display editor. vi: Invokes vi(C)
 a screen-oriented display editor. vi: Invokes view(C)
 effective user, real group, and effective group IDs. /real user, getuid(S)
 /getgid, getegid: Gets real user, effective user, real group, and/ getuid(S)
 for a pattern. grep, egrep, fgrep: Searches a file grep(C)
 input. soelim: Eliminates 'so's from nroff soelim(CT)
 line printers. enable: Turns on terminals and enable(C)
 accounting. acct: Enables or disables process acct(S)
 makekey: Generates an encryption key. makekey(M)
 locations in program. end, etext, edata: Last end(S)
 /getgrgid, getgrnam, setgrent, endgrent: Get group file entry. getgrent(S)
 eof: Determines end-of-file. eof(DOS)
 /getpwuid, getpwnam, setpwent, endpwent: Gets password file/ getpwent(S)
 utmp file entry. endutent, utmpname: Accesses getut(S)
 defopen, defread: Reads default entries. defopen(S)
 xlist, fxlist: Gets name list entries from files. xlist(S)
 nlist: Gets entries from name list. nlist(S)
 wtmp: Formats of utmp and wtmp entries. utmp, utmp(M)
 endgrent: Get group file entry. /getgrnam, setgrent, getgrent(S)
 endpwent: Gets password file entry. /getpwnam, setpwent, getpwent(S)
 utmpname: Accesses utmp file entry. endutent, getut(S)
 putpwent: Writes a password file entry. putpwent(S)
 unlink: Removes directory entry. unlink(S)
 command execution. env: Sets environment for env(C)
 environ: The user environment. environ(M)
 profile: Sets up an environment at login time. profile(M)
 environ: The user environment. environ(M)
 execution. env: Sets environment for command env(C)
 getenv: Gets value for environment name. getenv(S)
 putenv: Changes or adds value to environment. putenv(S)
 eof: Determines end-of-file. eof(DOS)
 Removes nroff/troff, tbl, and eqn constructs. deroff: deroff(CT)
 Formats mathematical text for/ eqn, neqn, checkeq, eqncheck: eqn(CT)
 text for/ eqn, neqn, checkeq, eqncheck: Formats mathematical eqn(CT)
 complementary error function. erf, erfc: Error function and erf(S)
 complementary error/ erf, erfc: Error function and erf(S)
 perror, sys_errlist, sys_nerr, ermo: Sends system error/ perror(S)
 error function. erf, erfc: Error function and complementary erf(S)
 Error function and complementary error function. erf, erfc: erf(S)
 source. mkstr: Creates an error message file from C mkstr(CP)
 dosxterr: Gets DOS error messages. dosxterr(DOS)
 sys_nerr, errno: Sends system error messages. /sys_errlist, perror(S)
 services, library routines and error numbers. /system Intro(S)
 matherr: Error-handling function. matherr(S)
 hashcheck: Finds spelling errors. /hashmake, spellin, spell(CT)

terminal line connection. dial: Establishes an out-going dial(S)
 setmnt: Establishes /etc/mnttab table. setmnt(C)
 setmnt: Establishes /etc/mnttab table. setmnt(C)
 program. end, etext, edata: Last locations in end(S)
 hypot, cabs: Determines Euclidean distance. hypot(S)
 expression. expr: Evaluates arguments as an expr(C)
 ex: Invokes a text editor. ex(C)
 execlp, execvp: Executes a/ execl, execv, execl, execve, exec(S)
 Executes a file. execl, execv, execl, execve, execlp, execvp: exec(S)
 execl, execv, execl, execve, execlp, execvp: Executes a file. exec(S)
 fixhdr: Changes executable binary file headers. fixhdr(C)
 execl, execve, execlp, execvp: Executes a file. execl, execv, exec(S)
 system: Executes a shell command. system(S)
 int86: Executes an interrupt. int86(DOS)
 int86x: Executes an interrupt. int86x(DOS)
 XENIX. uux: Executes command on remote uux(C)
 time. at, batch: Executes commands at a later at(C)
 times. cron: Executes commands at specified cron(C)
 XENIX system. remote: Executes commands on a remote remote(C)
 xargs: Constructs and executes commands. xargs(C)
 regex, regcmp: Compiles and executes regular expressions. regex(S)
 Sets environment for command execution. env: env(C)
 nap: Suspends execution for a short interval. nap(S)
 sleep: Suspends execution for an interval. sleep(C)
 sleep: Suspends execution for an interval. sleep(S)
 monitor: Prepares execution profile. monitor(S)
 profil: Creates an execution time profile. profil(S)
 execvp: Executes a file. execl, execv, execl, execve, execlp, exec(S)
 a file. execl, execv, execl, execve, execlp, execvp: Executes exec(S)
 execv, execl, execve, execlp, execvp: Executes a file. execl, exec(S)
 link: Links a new filename to an existing file. link(S)
 a new file or rewrites an existing one. creat: Creates creat(S)
 process. exit, _exit: Terminates a exit(S)
 exit, _exit: Terminates a process. exit(S)
 process. exit: Terminates the calling exit(DOS)
 false: Returns with a nonzero exit value. false(C)
 true: Returns with a zero exit value. true(C)
 Performs exponential, / exp, log, pow, sqrt, log10: exp(S)
 pcat, unpack: Compresses and expands files. pack, pack(C)
 usage. explain: Corrects language explain(CT)
 number into a mantissa and an exponent. /Splits floating-point frexp(S)
 /log, pow, sqrt, log10: Performs exponential, logarithm, power, / exp(S)
 expression. expr: Evaluates arguments as an expr(C)
 routines. regexp: Regular expression compile and match regexp(S)
 expr: Evaluates arguments as an expression. expr(C)
 regcmp: Compiles regular expressions. regcmp(CP)
 Compiles and executes regular expressions. regex, regcmp: regex(S)
 programs. xstr: Extracts strings from C xstr(CP)
 absolute value, floor, / floor, fabs, ceil, fmod: Performs floor(S)
 of inter-process communication facilities. /Reports the status ipcs(C)
 factor: Factor a number. factor(C)
 factor: Factor a number. factor(C)
 faliases: Micnet aliasing files. aliases(M)
 exit value. false: Returns with a nonzero false(C)
 abort: Generates an IOT fault. abort(S)

streams.	fclose, fcloseall: Closes	fclose(DOS)
flushes a stream.	fclose, fflush: Closes or	fclose(S)
fclose,	fcloseall: Closes streams.	fclose(DOS)
	fcntl: Controls open files.	fcntl(S)
conversions. ecvt,	fcvt, gcvt: Performs output	ecvt(S)
	fdisk: Maintain disk partitions.	fdisk(C)
fdopen, freopen,	fdopen: Opens a stream.	fopen(S)
/to machine related miscellaneous	features and files.	Intro(HW)
Introduction to miscellaneous	features and files. intro:	Intro(M)
Determines stream/ ferror,	feof, clearerr, fileno:	ferror(S)
Determines stream status.	ferror, feof, clearerr, fileno:	ferror(S)
nextkey: Performs/ dbminit,	fetch, store, delete, firstkey,	dbm(S)
stream. fclose,	flush: Closes or flushes a	fclose(S)
character from a stream.	fgetc, fgetchar: Gets a	fgetc(DOS)
word from a/ getc, getchar,	fgetc, getw: Gets character or	getc(S)
a stream. fgetc,	fgetchar: Gets a character from	fgetc(DOS)
stream. gets,	fgets: Gets a string from a	gets(S)
pattern. grep, egrep,	fgrep: Searches a file for a	grep(C)
Compares files too large for	diff. bdiff:	bdiff(C)
cut: Cuts out selected	fields of each line of a file.	cut(CT)
of file systems processed by	fsck. checklist: List	checklist(F)
times. utime: Sets	file access and modification	utime(S)
Determines accessibility of a	file. access:	access(S)
Format of per-process accounting	file. acct:	acct(F)
cpio: Copies	file archives in and out.	cpio(C)
for and processes a pattern in a	file. awk: Searches	awk(C)
chmod: Changes mode of a	file.	chmod(S)
Changes the owner and group of a	file. chown:	chown(S)
chsize: Changes the size of a	file.	chsize(S)
uupick: Public XENIX-to-XENIX	file copy. uuto,	uuto(C)
core: Format of core image	file.	core(F)
umask: Sets and gets	file creation mask.	umask(S)
ctags: Creates a tags	file.	ctags(CP)
fields of each line of a	file. cut: Cuts out selected	cut(CT)
dd: Converts and copies a	file.	dd(C)
a delta (change) to an SCCS	file. delta: Makes	delta(CP)
close: Closes a	file descriptor.	close(S)
dup, dup2: Duplicates an open	file descriptor.	dup(S)
	file: Determines file type.	file(C)
sact: Prints current SCCS	file editing activity.	sact(CP)
setgrent, endgrent: Get group	file entry. /getgrgid, getgrnam,	getgrent(S)
endpwent: Gets password	file entry. /getpwnam, setpwent,	getpwent(S)
utmpname: Accesses utmp	file entry. endutent,	getut(S)
putpwent: Writes a password	file entry.	putpwent(S)
execlp, execlvp: Executes a	file. /execvp, execl, execve,	exec(S)
filelength: Gets the length of a	file.	fileleng(DOS)
grep, egrep, fgrep: Searches a	file for a pattern.	grep(C)
open: Opens	file for reading or writing.	open(S)
writing. sopen: Opens a	file for shared reading and	sopen(DOS)
ar: Archive	file format.	ar(F)
intro: Introduction to	file formats.	Intro(F)
mkstr: Creates an error message	file from C source.	mkstr(CP)
group: Format of the group	file.	group(M)
grpcheck: Checks group	file.	grpcheck(C)
Changes executable binary	file headers. fixhdr:	fixhdr(C)

split: Splits a	file into pieces.	split(C)
a new filename to an existing	file. link: Links	link(S)
ln: Makes a link to a	file.	ln(C)
mem, kmem: Memory image	file.	mem(M)
The Micnet default commands	file. micnet:	micnet(M)
or a special or ordinary	file. mknod: Makes a directory, . . .	mknod(S)
Changes the format of a text	file. newform:	newform(C)
nl: Adds line numbers to a	file.	nl(C)
null: The null	file.	null(M)
/Finds the slot in the utmp	file of the current user.	ttyslot(S)
the access permissions of a	file or directory. /Changes	chmod(C)
rename: renames a	file or directory.	rename(DOS)
one. creat: Creates a new	file or rewrites an existing	creat(S)
passwd: The password	file.	passwd(M)
/ftell, rewind: Repositions a	file pointer in a stream.	fseek(S)
lseek: Moves read/write	file pointer.	lseek(S)
Gets the current position of the	file pointer. tell:	tell(DOS)
prs: Prints an SCCS	file.	prs(CP)
pwcheck: Checks password	file.	pwcheck(C)
read: Reads from a	file.	read(S)
locking: Locks or unlocks a	file region for reading or/	locking(S)
Removes a delta from an SCCS	file. rmdel:	rmdel(CP)
Compares two versions of an SCCS	file. sccsdiff:	sccsdiff(CP)
sccsfile: Format of an SCCS	file.	sccsfile(F)
Prints the size of an object	file. size:	size(CP)
stat, fstat: Gets	file status.	stat(S)
printable strings in an object	file. strings: Finds the	strings(CP)
mount: Mounts a	file structure.	mount(C)
umount: Dismounts a	file structure.	umount(C)
checksum and counts blocks in a	file. sum: Calculates	sum(C)
backup: Performs incremental	file system backup.	backup(C)
dump: Performs incremental	file system backup.	dump(C)
files. sysadmin: Performs	file system backups and restores . . .	sysadmin(C)
volume.	file system: Format of a system . . .	filesystem(F)
mkfs: Constructs a	file system.	mkfs(C)
mount: Mounts a	file system.	mount(S)
quot: Summarizes	file system ownership.	quot(C)
restor: Invokes incremental	file system restorer. restore,	restore(C)
ustat: Gets	file system statistics.	ustat(S)
mnttab: Format of mounted	file system table.	mnttab(F)
umount: Unmounts a	file system.	umount(S)
The Micnet system identification	file. systemid:	systemid(M)
haltsys: Closes out the	file systems and halts the CPU. . . .	haltsys(C)
fsck: Checks and repairs	file systems.	fsck(C)
fsck. checklist: List of	file systems processed by	checklist(F)
Delivers the last part of a	file. tail:	tail(C)
tmpfile: Creates a temporary	file.	tmpfile(S)
Creates a name for a temporary	file. tmpnam, tempnam:	tmpnam(S)
tsort: Sorts a	file topologically.	tsort(CP)
and modification times of a	file. touch: Updates access	touch(C)
ftw: Walks a	file tree.	ftw(S)
ttys: Login terminals	file.	ttys(M)
file: Determines	file type.	file(C)
Undoes a previous get of an SCCS	file. unget:	unget(CP)
Reports repeated lines in a	file. uniq:	uniq(C)

val: Validates an SCCS file.	val(CP)
write: Writes to a file.	write(S)
umask: Sets file-creation mode mask.	umask(C)
file. filelength: Gets the length of a	filelength(DOS)
ctermid: Generates a filename for a terminal.	ctermid(S)
mktemp: Makes a unique filename.	mktemp(S)
link: Links a new filename to an existing file.	link(S)
status. ferror, feof, clearerr, fileno: Determines stream	ferror(S)
csplit: Splits files according to context.	csplit(C)
and prints process accounting files. acctcom: Searches for	acctcom(C)
rcp: Copies files across XENIX systems.	rcp(C)
Creates and administers SCCS files. admin:	admin(CP)
faliases: Micnet aliasing files.	aliases(M)
mv: Moves or renames files and directories.	mv(C)
bfs: Scans big files.	bfs(C)
cat: Concatenates and displays files.	cat(C)
cmp: Compares two files.	cmp(C)
lines common to two sorted files. comm: Selects or rejects	comm(C)
copy: Copies groups of files.	copy(C)
cp: Copies files.	cp(C)
diff3: Compares three files.	diff3(C)
diff: Compares two text files.	diff(C)
Marks differences between files. diffmk:	diffmk(CT)
dos: Accesses DOS files.	dos(C)
dos: Accesses DOS files.	doscat(C)
dos: Accesses DOS files.	doscp(C)
dos: Accesses DOS files.	dosdir(C)
dos: Accesses DOS files.	dosls(C)
dos: Accesses DOS files.	dosrm(C)
dos: Accesses DOS files.	dosrmdir(C)
fcntl: Controls open files.	fcntl(S)
find: Finds files.	find(C)
selected parts of object files. hdr: Displays	hdr(CP)
hd: Displays files in hexadecimal format.	hd(C)
od: Displays files in octal format.	od(C)
miscellaneous features and files. /to machine related	Intro(HW)
to miscellaneous features and files. intro: Introduction	Intro(M)
semaphores and record locking on files. lockf: Provide	lockf(S)
mknod: Builds special files.	mknod(C)
dumpdir: Prints the names of files on a backup archive.	dumpdir(C)
imprint: print text files on an IMAGEN printer.	imprint(C)
imprint: print text files on an IMAGEN printer.	imprint(CT)
pr: Prints files on the standard output.	pr(C)
rm, rmdir: Removes files or directories.	rm(C)
unpack: Compresses and expands files. pack, pcat,	pack(C)
paste: Merges lines of files.	paste(CT)
access and modification dates of files. settime: Changes the	settime(C)
sdiff: Compares files side-by-side.	sdiff(C)
sort: Sorts and merges files.	sort(C)
file system backups and restores files. sysadmin: Performs	sysadmin(C)
tar: Archives files.	tar(C)
for printing. lpr: Sends files to the lineprinter queue	lpr(C)
bdiff: Compares files too large for diff.	bdiff(C)
top.next: The Micnet topology files. top,	top(M)
Administer UUCP control files. uinstall:	uinstall(C)

what: Identifies files.	what(C)
Gets name list entries from files. xlist, fxlist:	xlist(S)
col: Filters reverse linefeeds.	col(CT)
documents formatted with the mm macros. mm: Prints	mm(CT)
find: Finds files.	find(C)
hyphen: Finds hyphenated words.	hyphen(CT)
finger: Finds information about users.	finger(C)
look: Finds lines in a sorted list.	look(CT)
logname: Finds login name of user.	logname(S)
object library. lorder: Finds ordering relation for an	lorder(CP)
hashmake, spellin, hashcheck: Finds spelling errors. spell,	spell(CT)
ttyname, isatty: Finds the name of a terminal.	ttyname(S)
an object file. strings: Finds the printable strings in	strings(CP)
of the current user. ttyslot: Finds the slot in the utmp file	ttyslot(S)
users. finger: Finds information about	finger(C)
dbmunit, fetch, store, delete, firstkey, nextkey: Performs/	dbm(S)
/Prints formatted output of a varargs argument list.	vprintf(S)
hd: Internal fixed disk drive.	hd(HW)
flaw map. badtrk - Scans fixed disk for flaws and creates	badtrk(M)
binary file headers. fixhdr: Changes executable	fixhdr(C)
fixed disk for flaws and creates flaw map. badtrk - Scans	badtrk(M)
badtrk - Scans fixed disk for flaws and creates flaw map.	badtrk(M)
frexp, ldexp, modf: Splits floating-point number into a/	frexp(S)
/fmod: Performs absolute value, floor, ceiling and remainder/	floor(S)
Performs absolute value, floor,/ floor, fabs, ceil, fmod:	floor(S)
diskcmp: Copies or compares floppy disks. diskcp,	diskcp(C)
cflow: Generates C flow graph.	cflow(CP)
buffers. flushall: Flushes all output	flushall(DOS)
fclose, fflush: Closes or flushes a stream.	fclose(S)
flushall: Flushes all output buffers.	flushall(DOS)
CPU. shutdown: Flushes block I/O and halts the	shutdown(S)
floor,/ floor, fabs, ceil, fmod: Performs absolute value,	floor(S)
stream. fopen, freopen, fdopen: Opens a	fopen(S)
fork: Creates a new process.	fork(S)
ar: Archive file format.	ar(F)
backup: Incremental dump tape format.	backup(F)
dump: Incremental dump tape format.	dump(F)
86rel: Intel 8086 Relocatable Format for Object Modules.	86rel(F)
Displays files in hexadecimal format. hd:	hd(C)
od: Displays files in octal format.	od(C)
dir: Format of a directory.	dir(F)
file system: Format of a system volume.	filesystem(F)
newform: Changes the format of a text file.	newform(C)
inode: Format of an inode.	inode(F)
scsfile: Format of an SCCS file.	scsfile(F)
editor output. a.out: Format of assembler and link	a.out(F)
core: Format of core image file.	core(F)
cpio: Format of cpio archive.	cpio(F)
table. mnttab: Format of mounted file system	mnttab(F)
file. acct: Format of per-process accounting	acct(F)
group: Format of the group file.	group(M)
tar: archive format.	tar(F)
cscanf: Converts and formats console input.	cscanf(DOS)
fscanf, sscanf: Converts and formats input. scanf,	scanf(S)
intro: Introduction to file formats.	Intro(F)

eqn, neqn, checkeq, eqncheck:	Formats mathematical text for/	eqn(CT)
neqn:	Formats mathematics.	neqn(CT)
entries. utmp, wtmp:	Formats of utmp and wtmp	utmp(M)
cprintf:	Formats output.	cprintf(DOS)
printf, fprintf, sprintf:	Formats output.	printf(S)
troff. tbl:	Formats tables for nroff or	tbl(CT)
fprintf, vsprintf:	Prints formatted output of a/ vprintf,	vprintf(S)
macros. mm:	Prints documents formatted with the mm	mm(CT)
nroff: A text	formatter.	nroff(CT)
ratfor: Converts Rational	FORTRAN into standard FORTRAN.	ratfor(CP)
Rational FORTRAN into standard	FORTRAN. ratfor: Converts	ratfor(CP)
and segment.	fp_off, fp_seg: Return offset	fp_seg(DOS)
output. printf,	fprintf, sprintf: Formats	printf(S)
segment. fp_off,	fp_seg: Return offset and	fp_seg(DOS)
character to a stream.	fputc, fputchar: Write a	fputc(DOS)
word on a/ putc, putchar,	fputc, putw: Puts a character or	putc(S)
stream. fputc,	fputchar: Write a character to a	fputc(DOS)
stream. puts,	fputs: Puts a string on a	puts(S)
binary input and output.	fread, fwrite: Performs buffered	fread(S)
main memory. malloc,	free, realloc, calloc: Allocates	malloc(S)
fopen,	freopen, fdopen: Opens a stream.	fopen(S)
floating-point number into a/	frexp, ldexp, modf: Splits	frexp(S)
formats input. scanf,	fscanf, sscanf: Converts and	scanf(S)
systems.	fseek: Checks and repairs file	fseek(C)
Repositions a file pointer in a/	fseek, ftell, rewind:	fseek(S)
stat,	fstat: Gets file status.	stat(S)
file pointer in a/ fseek,	ftell, rewind: Repositions a	fseek(S)
time,	ftime: Gets time and date.	time(S)
communication package.	ftok: Standard interprocess	stdipc(S)
function. erf, erfc: Error	function and complementary error	erf(S)
function and complementary error	function. erf, erfc: Error	erf(S)
gamma: Performs log gamma	function.	gamma(S)
setkey: Assigns the	function keys.	setkey(M)
matherr: Error-handling	function.	matherr(S)
jn, y0, y1, yn: Performs Bessel	functions. bessell, j0, j1,	bessel(S)
Performs screen and cursor	functions. curses:	curses(S)
nextkey: Performs database	functions. /delete, firstkey,	dbm(S)
logarithm, power, square root	functions. /exponential,	exp(S)
floor, ceiling and remainder	functions. /absolute value,	floor(S)
to DOS cross development	functions. intro: Introduction	intro(DOS)
cosh, tanh: Performs hyperbolic	functions. sinh,	sinh(S)
tgoto, tputs: Performs terminal	functions. /tgetflag, tgetstr,	termcap(S)
atan2: Performs trigonometric	functions. /asin, acos, atan,	trig(S)
input and output. fread,	fwrite: Performs buffered binary	fread(S)
from files. xlist,	fxlist: Gets name list entries	xlist(S)
gamma: Performs log	gamma function.	gamma(S)
function.	gamma: Performs log gamma	gamma(S)
conversions. ecvt, fcvt,	gcvt: Performs output	ecvt(S)
adb: Invokes a	general-purpose debugger.	adb(CP)
terminal. ctermid:	Generates a filename for a	ctermid(S)
ptx:	Generates a permuted index.	ptx(CT)
random:	Generates a random number.	random(C)
rand, srand:	Generates a random number.	rand(S)
makekey:	Generates an encryption key.	makekey(M)

abort: Generates an IOT fault. abort(S)
 cflow: Generates C flow graph. cflow(CP)
 cross-reference. cxref: Generates C program cxref(CP)
 numbers. ncheck: Generates names from inode ncheck(C)
 analysis. lex: Generates programs for lexical lex(CP)
 srand48, seed48, lcong48: Generates uniformly distributed. drand48(S)
 Micnet alias hash table generator. aliahash: aliahash(M)
 character or word from a/ getc, getchar, fgetc, getw: Gets getc(S)
 getch: Gets a character. getch(DOS)
 character or word from a/ getch, getchar, fgetc, getw: Gets getc(S)
 character. getche: Gets and echoes a getche(DOS)
 current working directory. getcwd: Get the pathname of getcwd(S)
 getuid, geteuid, getgid, getegid: Gets real user,/ getuid(S)
 environment name. getenv: Gets value for getenv(S)
 real user, effective/ getuid, geteuid, getgid, getegid: Gets getuid(S)
 effective/ getuid, geteuid, getgid, getegid: Gets real user, getuid(S)
 setgrent, endgrent: Get group/ getgrent, getgrgid, getgrnam, getgrent(S)
 endgrent: Get group/ getgrent, getgrgid, getgrnam, setgrent, getgrent(S)
 Get group/ getgrent, getgrgid, getgrnam, setgrent, endgrent: getgrent(S)
 getlogin: Gets login name. getlogin(S)
 argument vector. getopt: Gets option letter from getopt(S)
 getopt: Parses command options. getopt(C)
 getpass: Reads a password. getpass(S)
 process group, and/ getpid, getpgrp, getppid: Gets process, getpid(S)
 process, process group, and/ getpid, getpgrp, getppid: Gets getpid(S)
 group, and/ getpid, getpgrp, getppid: Gets process, process getpid(S)
 user ID. getpw: Gets password for a given getpw(S)
 setpwent, endpwent: Gets/ getpwent, getpwuid, getpwnam, getpwent(S)
 Gets/ getpwent, getpwuid, getpwnam, setpwent, endpwent: getpwent(S)
 endpwent: Gets/ getpwent, getpwuid, getpwnam, setpwent, getpwent(S)
 fgetc, fgetchar: Gets a character from a stream. fgetc(DOS)
 getch: Gets a character. getch(DOS)
 shmget: Gets a shared memory segment. shmget(S)
 gets, fgets: Gets a string from a stream. gets(S)
 input. gets: Gets a string from the standard gets(CP)
 getche: Gets and echoes a character. getche(DOS)
 ulimit: Gets and sets user limits. ulimit(S)
 getc, getchar, fgetc, getw: Gets character or word from a/ getc(S)
 dosexterr: Gets DOS error messages. dosexterr(DOS)
 nlist: Gets entries from name list. nlist(S)
 a stream. gets, fgets: Gets a string from gets(S)
 umask: Sets and gets file creation mask. umask(S)
 stat, fstat: Gets file status. stat(S)
 ustat: Gets file system statistics. ustat(S)
 standard input. gets: Gets a string from the gets(CP)
 getlogin: Gets login name. getlogin(S)
 logname: Gets login name. logname(C)
 msgget: Gets message queue. msgget(S)
 files. xlist, fxlist: Gets name list entries from xlist(S)
 system. uname: Gets name of current XENIX uname(S)
 vector. getopt: Gets option letter from argument getopt(S)
 /getpwnam, setpwent, endpwent: Gets password file entry. getpwent(S)
 ID. getpw: Gets password for a given user getpw(S)
 times. times: Gets process and child process times(S)
 getpid, getpgrp, getppid: Gets process, process group, and/ getpid(S)

systemid: The Micnet system	identification file.	systemid(M)
devnm: Identifies device name.	devnm(C)
what: Identifies files.	what(C)
id: Prints user and group	IDs and names.	id(C)
group, and parent process	IDs. /Gets process, process	getpid(S)
realgroup, and effective group	IDs. /real user, effective user, . . .	getuid(S)
setgid: Sets user and group	IDs. setuid,	setuid(S)
core: Format of core	image file.	core(F)
mem, kmem: Memory	image file.	mem(M)
imprint: print text files on an	IMAGEN printer.	imprint(C)
imprint: print text files on an	IMAGEN printer.	imprint(CT)
nohup: Runs a command	immune to hangups and quits. . . .	nohup(C)
ssignal, gsignal:	Implements software signals. . . .	ssignal(S)
IMAGEN printer.	imprint: print text files on an	imprint(C)
IMAGEN printer.	imprint: print text files on an	imprint(CT)
backup:	Incremental dump tape format. . . .	backup(F)
dump:	Incremental dump tape format. . . .	dump(F)
backup: Performs	incremental file system backup. . . .	backup(C)
dump: Performs	incremental file system backup. . . .	dump(C)
restore, restor: Invokes	incremental file system/	restore(C)
ptx: Generates a permuted	index.	ptx(CT)
prints lineprinter status	information. lpstat:	lpstat(C)
pstat: Reports system	information.	pstat(C)
initialization.	init: Process control	init(M)
init: Process control	initialization.	init(M)
process. popen, pclose:	Initiates I/O to or from a	popen(S)
clri: Clears	inode.	clri(C)
inode: Format of an	inode: Format of an inode.	inode(F)
ncheck: Generates names from	inode.	inode(F)
inode numbers.	ncheck(C)
inp: Returns a byte.	inp(DOS)
input and output. fread,	fread(S)
input and output. stdio:	stdio(S)
input. cscanf:	scanf(DOS)
input. gets:	gets(CP)
input. scanf, fscanf,	scanf(S)
input. soelim:	soelim(CT)
input stream. ungetc:	ungetc(S)
inquiry and job control.	uustat(C)
install: Installation shell	install(M)
install: Installation shell script.	install(M)
creatsem: Creates an	instance of a binary semaphore. . . .	creatsem(S)
int86: Executes an interrupt.	int86(DOS)
int86x: Executes an interrupt.	int86x(DOS)
call. intdos: Invokes a DOS system	intdos(DOS)
call. intdosx: Invokes a DOS system	intdosx(DOS)
abs: Returns an	integer absolute value.	abs(S)
/l64a: Converts between long	integer and base 64 ASCII.	a64l(S)
sputl, sgetl: Accesses long	integer data in a/	sputl(S)
the absolute value of a long	integer. labs: Returns	labs(DOS)
atoi, atol: Converts string to	integer. strtol,	strtol(S)
/lto13: Converts between 3-byte	integers and long integers.	l3tol(S)
itoa: Converts numbers to	integers.	itoa(DOS)
between 3-byte integers and long	integers. /lto13: Converts	l3tol(S)
ltoa: Converts long	integers to characters.	ltoa(DOS)

for Object Modules. 86rel: Intel 8086 Relocatable Format . . . 86rel(F)
termio: General terminal interface. termio(M)
/tty1[A-H], tty2[a-h], tty2[A-H]: Interface to serial ports. serial(HW)
tty: Special terminal interface. tty(M)
lp1, lp2: Line printer device interfaces. lp, lp0, lp(HW)
hd: Internal fixed disk drive. hd(HW)
spline: Interpolates smooth curve. spline(CP)
a restricted shell (command interpreter). rsh: Invokes rsh(C)
sh: Invokes the shell command interpreter. sh(C)
shV: Invokes the shell command interpreter. shV(C)
csh: Invokes a shell command interpreter with C-like syntax. csh(C)
ipcs: Reports the status of inter-process communication/ ipcs(C)
package. ftok: Standard interprocess communication stdipc(S)
pipe: Creates an interprocess pipe. pipe(S)
int86: Executes an interrupt. int86(DOS)
int86x: Executes an interrupt. int86x(DOS)
Suspend execution for a short interval. nap: nap(S)
sleep: Suspend execution for an interval. sleep(C)
sleep: Suspend execution for an interval. sleep(S)
services, library routines and/ intro: Introduces system Intro(S)
processing commands. intro: Introduces text Intro(CT)
commands. intro: Introduces XENIX Intro(C)
Development System commands. intro: Introduces XENIX Intro(CP)
development functions. intro: Introduction to DOS cross intro(DOS)
formats. intro: Introduction to file Intro(F)
related miscellaneous features/ intro: Introduction to machine Intro(HW)
miscellaneous features and/ intro: Introduction to Intro(M)
library routines and/ intro: Introduces system services, Intro(S)
commands. intro: Introduces text processing Intro(CT)
intro: Introduces XENIX commands. Intro(C)
System commands. intro: Introduces XENIX Development Intro(CP)
development functions. intro: Introduction to DOS cross intro(DOS)
intro: Introduction to file formats. Intro(F)
miscellaneous features/ intro: Introduction to machine related Intro(HW)
features and files. intro: Introduction to miscellaneous Intro(M)
bc: Invokes a calculator. bc(C)
yacc: Invokes a compiler-compiler. yacc(CP)
bdos: Invokes a DOS system call. bdos(DOS)
intdos: Invokes a DOS system call. intdos(DOS)
intdosx: Invokes a DOS system call. intdosx(DOS)
debugger. adb: Invokes a general-purpose adb(CP)
m4: Invokes a macro processor. m4(CP)
calendar: Invokes a reminder service. calendar(C)
(command interpreter). rsh: Invokes a restricted shell rsh(C)
red: Invokes a restricted version of. red(C)
display editor. vi: Invokes a screen-oriented vedit(C)
display editor. vi: Invokes a screen-oriented vi(C)
display editor. vi: Invokes a screen-oriented view(C)
interpreter with C-like/ csh: Invokes a shell command csh(C)
ex: Invokes a text editor. ex(C)
calculator. dc: Invokes an arbitrary precision dc(C)
restorer. restore, restor: Invokes incremental file system restore(C)
cc: Invokes the C Compiler. cc(CP)
ld: Invokes the link editor. ld(CP)
ld: Invokes the link editor. ld(M)

interpreter. sh: Invokes the shell command sh(C)
 interpreter. shV: Invokes the shell command shV(C)
 sed: Invokes the stream editor. sed(C)
 ed: Invokes the text editor. ed(C)
 masn: Invokes the XENIX assembler. . . . masn(CP)
 shutdown: Flushes block I/O and halts the CPU. shutdown(S)
 popen, pclose: Initiates I/O to or from a process. popen(S)
 devices. ioctl: Controls character ioctl(S)
 abort: Generates an IOT fault. abort(S)
 semaphore set or shared memory. ipcrm: Removes a message queue, . . . ipcrm(C)
 inter-process communication/ ipc: Reports the status of ipc(C)
 /islower, isdigit, isxdigit, isalnum, isspace, ispunct,/ ctype(S)
 isdigit, isxdigit,/ ctype, isalpha, isupper, islower, ctype(S)
 /isprint, isgraph, iscntrl, isascii: Classifies characters. ctype(S)
 device. isatty: Checks for a character isatty(DOS)
 terminal. ttyname, isatty: Finds the name of a ttyname(S)
 /ispunct, isprint, isgraph, iscntrl, isascii: Classifies/ ctype(S)
 /isalpha, isupper, islower, isdigit, isxdigit, isalnum,/ ctype(S)
 /isspace, ispunct, isprint, isgraph, iscntrl, isascii:/ ctype(S)
 ctype, isalpha, isupper, islower, isdigit, isxdigit,/ ctype(S)
 /isalnum, isspace, ispunct, isprint, isgraph, iscntrl,/ ctype(S)
 /isxdigit, isalnum, isspace, ispunct, isprint, isgraph,/ ctype(S)
 /isdigit, isxdigit, isalnum, isspace, ispunct, isprint,/ ctype(S)
 isxdigit,/ ctype, isalpha, isupper, islower, isdigit, ctype(S)
 /isupper, islower, isdigit, isxdigit, isalnum, isspace,/ ctype(S)
 news: Print news items. news(C)
 integers. itoa: Converts numbers to itoa(DOS)
 Bessel functions. bessel, j0, j1, jn, y0, y1, yn: Performs bessel(S)
 Bessel functions. bessel, j0, j1, jn, y0, y1, yn: Performs bessel(S)
 functions. bessel, j0, j1, jn, y0, y1, yn: Performs Bessel bessel(S)
 join: Joins two relations. join(C)
 keystroke. kbhit: Checks the console for a kbhit(DOS)
 makekey: Generates an encryption key. makekey(M)
 keyboard: The console keyboard. keyboard(HW)
 keyboard: The console keyboard. keyboard(HW)
 setkey: Assigns the function keys. setkey(M)
 kbhit: Checks the console for a keystroke. kbhit(DOS)
 process or a group of/ kill: Sends a signal to a kill(S)
 kill: Terminates a process. kill(C)
 mem, kmem: Memory image file. mem(M)
 contents of directory. l: Lists information about l(C)
 3-byte integers and long/ l3tol, ltol3: Converts between l3tol(S)
 integer and base 64/ a64l, l64a: Converts between long a64l(S)
 of a long integer. labs: Returns the absolute value labs(DOS)
 cpp: The C language preprocessor. cpp(CP)
 lint: Checks C language usage and syntax. lint(CP)
 diction: Checks language usage. diction(CT)
 explain: Corrects language usage. explain(CT)
 columns. lc: Lists directory contents in lc(C)
 distributed. srand48, seed48, lcong48: Generates uniformly . . . drand48(S)
 ld: Invokes the link editor. ld(CP)
 ld: Invokes the link editor. ld(M)
 floating-point number/ frexp, ldexp, modf: Splits frexp(S)
 filelength: Gets the length of a file. fileleng(DOS)

strlen: Returns the length of a string.	strlen(DOS)
getopt: Gets option letter from argument vector.	getopt(S)
banner: Prints large letters.	banner(C)
lexical analysis. lex: Generates programs for	lex(CP)
lex: Generates programs for lexical analysis.	lex(CP)
and update. lsearch, lfind: Performs linear search	lsearch(S)
ar: Maintains archives and libraries.	ar(CP)
Converts archives to random libraries. ranlib:	ranlib(CP)
ordering relation for an object library. lorder: Finds	lorder(CP)
/Introduces system services, library routines and error/	Intro(S)
ulimit: Gets and sets user limits.	ulimit(S)
line: Reads one line.	line(C)
lsearch, lfind: Performs linear search and update.	lsearch(S)
col: Filters reverse linefeeds.	col(CT)
cancel: Send/cancel requests to lineprinter. lp, lpr,	lp(C)
lpr: Sends files to the lineprinter queue for printing.	lpr(C)
lpshut, lpmove: Starts/stops the lineprinter request. lpsched,	lpsched(C)
lpadmin: Configures the lineprinter spooling system.	lpadmin(C)
lpstat: prints lineprinter status information.	lpstat(C)
lpinit: Adds new lineprinters to system.	lpinit(C)
files. comm: Selects or rejects lines common to two sorted	comm(C)
uniq: Reports repeated lines in a file.	uniq(C)
look: Finds lines in a sorted list.	look(CT)
head: Prints the first few lines of a stream.	head(C)
paste: Merges lines of files.	paste(CT)
wc: Counts lines, words and characters.	wc(C)
ld: Invokes the link editor.	ld(CP)
ld: Invokes the link editor.	ld(M)
a.out: Format of assembler and link editor output.	a.out(F)
existing file. link: Links a new filename to an	link(S)
ln: Makes a link to a file.	ln(C)
dosld: XENIX to MS-DOS cross linker.	dosld(CP)
existing file. link: Links a new filename to an	link(S)
and syntax. lint: Checks C language usage	lint(CP)
xlist, fxlist: Gets name list entries from files.	xlist(S)
look: Finds lines in a sorted list.	look(CT)
nlist: Gets entries from name list.	nlist(S)
nm: Prints name list.	nm(CP)
byfsck. checklist: List of file systems processed	checklist(F)
terminals: List of supported terminals.	terminals(M)
varargs: Variable argument list.	varargs(F)
of a varargs argument list. /Prints formatted output	vprintf(S)
cref: Makes a cross-reference listing.	cref(CP)
columns. lc: Lists directory contents in	lc(C)
of directory. l: Lists information about contents	l(C)
who: Lists who is on the system.	who(C)
ln: Makes a link to a file.	ln(C)
tzset: Converts date and/ ctime, localtime, gmtime, asctime,	ctime(S)
end, etext, edata: Last locations in program.	end(S)
memory. lock: Locks a process in primary	lock(S)
memory. plock: Lock process, text, or data in	plock(S)
record locking on files. lockf: Provide semaphores and	lockf(S)
region for reading or writing. locking: Locks or unlocks a file	locking(S)
Provide semaphores and record locking on files. lockf:	lockf(S)
memory. lock: Locks a process in primary	lock(S)

for reading or/ locking: Locks or unlocks a file region . . . locking(S)
 gamma: Performs log gamma function. gamma(S)
 exponential, logarithm,/ exp, log, pow, sqrt, log10: Performs . . . exp(S)
 logarithm,/ exp, log, pow, sqrt, log10: Performs exponential, . . . exp(S)
 /log10: Performs exponential, logarithm, power, square root/ . . . exp(S)
 mkuser: Adds a login ID to the system. mkuser(C)
 getlogin: Gets login name. getlogin(S)
 logname: Gets login name. logname(C)
 cuserid: Gets the login name of the user. cuserid(S)
 logname: Finds login name of user. logname(S)
 passwd: Changes login password. passwd(C)
 ttys: Login terminals file. ttys(M)
 Sets up an environment at login time. profile: profile(M)
 user. logname: Finds login name of . . . logname(S)
 logname: Gets login name. logname(C)
 newgrp: Logs user in to a new group. newgrp(C)
 "goto", setjmp, longjmp: Performs a nonlocal . . . setjmp(S)
 for an object library. lorder: Finds ordering relation . . . lorder(CP)
 uppercase. strupr: Converts lowercase characters to . . . strupr(DOS)
 Converts uppercase characters to lowercase. strlwr: strlwr(DOS)
 device interfaces. lp, lp0, lp1, lp2: Line printer . . . lp(HW)
 requests to lineprinter. lp, lpr, cancel: Send/cancel . . . lp(C)
 device interfaces. lp, lp0, lp1, lp2: Line printer . . . lp(HW)
 interfaces. lp, lp0, lp1, lp2: Line printer device . . . lp(HW)
 interfaces. lp, lp0, lp1, lp2: Line printer device . . . lp(HW)
 lineprinter spooling system. lpadm: Configures the . . . lpadm(C)
 system. lpinit: Adds new lineprinters to . . . lpinit(C)
 lineprinter/ lpsched, lpshut, lpmove: Starts/stops the . . . lpsched(C)
 requests to lineprinter. lp, lpr, cancel: Send/cancel . . . lp(C)
 lineprinter queue for printing. lpr: Sends files to the . . . lpr(C)
 Starts/stops the lineprinter/ lpsched, lpshut, lpmove: . . . lpsched(C)
 lineprinter request. lpsched, lpshut, lpmove: Starts/stops the . . . lpsched(C)
 status information. lpstat: prints lineprinter . . . lpstat(C)
 contents of directories. ls: Gives information about . . . ls(C)
 search and update. lsearch, lfind: Performs linear . . . lsearch(S)
 pointer. lseek: Moves read/write file . . . lseek(S)
 characters. ltoa: Converts long integers to . . . ltoa(DOS)
 integers and long/ l3tol, ltol3: Converts between 3-byte . . . l3tol(S)
 m4: Invokes a macro processor. m4(CP)
 machine. Machine: Description of host . . . machine(HW)
 Machine: Description of host machine. machine(HW)
 features/ intro: Introduction to machine related miscellaneous . . . Intro(HW)
 Accesses long integer data in a machine-independent. /sgetl: . . . sputl(S)
 m4: Invokes a macro processor. m4(CP)
 mmcheck: Checks usage of MM macros. checkmm, checkmm(CT)
 formatted with the mm macros. mm: Prints documents . . . mm(CT)
 Sends, reads or disposes of mail. mail: mail(C)
 of mail. mail: Sends, reads or disposes . . . mail(C)
 daemon.mn: Micnet mailer daemon. daemon.mn(M)
 free, realloc, calloc: Allocates main memory. malloc, malloc(S)
 fdisk: Maintain disk partitions. fdisk(C)
 libraries. ar: Maintains archives and ar(CP)
 regenerates groups of/ make: Maintains, updates, and make(CP)
 key. makekey: Generates an encryption . . . makekey(M)
 cref: Makes a cross-reference listing. cref(CP)

SCCS file. delta: Makes a delta (change) to an delta(CP)
 mkdir: Makes a directory. mkdir(C)
 or ordinary file. mknod: Makes a directory, or a special . . . mknod(S)
 ln: Makes a link to a file. ln(C)
 mktemp: Makes a unique filename. mktemp(S)
 another user. su: Makes the user a super-user or . . . su(C)
 Allocates main memory. malloc, free, realloc, calloc: malloc(S)
 tsearch, tfind, tdelete, twalk: Manages binary search trees. . . . tsearch(S)
 hsearch, hcreate, hdestroy: Manages hash search tables. . . . hsearch(S)
 /floating-point number into a mantissa and an exponent. frexp(S)
 disk for flaws and creates flaw map. badtrk - Scans fixed badtrk(M)
 ascii: Map of the ASCII character set. ascii(M)
 Configure console screen/ mapkey, mapscrn, mapstr: mapkey(M)
 mapstr: Configure console screen mapping. mapkey, mapscrn, mapkey(M)
 console screen mapping. mapkey, mapscrn, mapstr: Configure mapkey(M)
 mapping. mapkey, mapscrn, mapstr: Configure console screen mapkey(M)
 diffmk: Marks differences between files. . . . diffmk(CT)
 umask: Sets file-creation mode mask. umask(C)
 Sets and gets file creation mask. umask: umask(S)
 assembler. masm: Invokes the XENIX masm(CP)
 master: Master device information table. . . . master(F)
 information table. master: Master device master(F)
 Regular expression compile and match routines. regexp: regexp(S)
 /neqn, checkeq, eqncheck: Formats mathematical text for nroff,/ eqn(CT)
 neqn: Formats mathematics. neqn(CT)
 function. matherr: Error-handling matherr(S)
 mem, kmem: Memory image file. mem(M)
 queue, semaphore set or shared memory. /Removes a message ipcrm(C)
 lock: Locks a process in primary memory. lock(S)
 realloc, calloc: Allocates main memory. malloc, free, malloc(S)
 shmctl: Controls shared memory operations. shmctl(S)
 shmop: Performs shared memory operations. shmop(S)
 Lock process, text, or data in memory. plock: plock(S)
 shmget: Gets a shared memory segment. shmget(S)
 sort: Sorts and merges files. sort(C)
 paste: Merges lines of files. paste(CT)
 sent to a terminal. msg: Permits or denies messages msg(C)
 msgctl: Provides message control operations. msgctl(S)
 mkstr: Creates an error message file from C source. mkstr(CP)
 msgop: Message operations. msgop(S)
 msgget: Gets message queue. msgget(S)
 shared memory. ipcrm: Removes a message queue, semaphore set or ipcrm(C)
 console messages. messages: Description of system messages(M)
 dosexterr: Gets DOS error messages. dosexterr(DOS)
 Description of system console messages. messages: messages(M)
 errno: Sends system error messages. /sys_nerr, perror(S)
 msg: Permits or denies messages sent to a terminal. msg(C)
 generator. aliahash: Micnet alias hash table aliahash(M)
 faliases: Micnet aliasing files. aliases(M)
 micnet: The Micnet default commands file. micnet(M)
 daemon.mn: Micnet mailer daemon. daemon.mn(M)
 file. systemid: The Micnet system identification systemid(M)
 commands file. micnet: The Micnet default micnet(M)
 top, top.next: The Micnet topology files. top(M)

/Introduction to machine related	miscellaneous features and/	Intro(HW)
files. intro: Introduction to	miscellaneous features and	Intro(M)
	mkdir: Creates a new directory.	mkdir(DOS)
	mkdir: Makes a directory.	mkdir(C)
	mkfs: Constructs a file system.	mkfs(C)
	mknod: Builds special files.	mknod(C)
special or ordinary file.	mknod: Makes a directory, or a	mknod(S)
file from C source.	mkstr: Creates an error message	mkstr(CP)
	mktemp: Makes a unique filename.	mktemp(S)
system.	mkuser: Adds a login ID to the	mkuser(C)
mmcheck: Checks usage of	MM macros. checkmm,	checkmm(CT)
with the <i>mm</i> macros.	mm: Prints documents formatted	mm(CT)
macros. checkmm,	mmcheck: Checks usage of MM	checkmm(CT)
	mmt: Typesets documents.	mmt(CT)
system table.	mnttab: Format of mounted file	mnttab(F)
umask: Sets file-creation	mode mask.	umask(C)
chmod: Changes	mode of a file.	chmod(S)
setmode: Sets translation	mode.	setmode(DOS)
dial: Dials a	modem.	dial(M)
getty: Sets terminal type,	modes, speed, and line/	getty(M)
tset: Sets terminal	modes.	tset(C)
number into a/ frexp, ldexp,	modf: Splits floating-point	frexp(S)
settime: Changes the access and	modification dates of files.	settime(C)
touch: Updates access and	modification times of a file.	touch(C)
utime: Sets file access and	modification times.	utime(S)
Relocatable Format for Object	Modules. 86rel: Intel 8086	86rel(F)
profile.	monitor: Prepares execution	monitor(S)
uusub: Monitor uucp network.		uusub(C)
	mount: Mounts a file structure.	mount(C)
	mount: Mounts a file system.	mount(S)
mnttab: Format of	mounted file system table.	mnttab(F)
mount: Mounts a file structure.		mount(C)
mount: Mounts a file system.		mount(S)
specific address.	movedata: Copies bytes from a	movedata(DOS)
mvdire: Moves a directory.		mvdire(C)
directories. mv: Moves or renames files and		mv(C)
lseek: Moves read/write file pointer.		lseek(S)
dosld: XENIX to	MS-DOS cross linker.	dosld(CP)
operations.	msgctl: Provides message control	msgctl(S)
	msgget: Gets message queue.	msgget(S)
	msgop: Message operations.	msgop(S)
directories.	mv: Moves or renames files and	mv(C)
	mvdire: Moves a directory.	mvdire(C)
devnm: Identifies device	name.	devnm(C)
Gets value for environment	name. getenv:	getenv(S)
getlogin: Gets login	name.	getlogin(S)
logname: Gets login	name.	logname(C)
pwd: Prints working directory	name.	pwd(C)
tty: Gets the terminal's	name.	tty(C)
ncheck: Generates	names from inode numbers.	ncheck(C)
basename: Removes directory	names from pathnames.	basename(C)
Prints user and group IDs and	names. id:	id(C)
archive. dumpdir: Prints the	names of files on a backup	dumpdir(C)
term: Conventional	names.	term(CT)
short interval.	nap: Suspends execution for a	nap(S)

access to a resource/ waitsem:	nwaitsem: Awaits and checks	waitsem(S)
inode numbers.	ncheck: Generates names from	ncheck(C)
mathematical text for/ eqn,	neqn, checkeq, eqncheck: Formats	eqn(CT)
	neqn: Formats mathematics.	neqn(CT)
network.	netutil: Administers the XENIX	netutil(C)
netutil: Administers the XENIX	network.	netutil(C)
uusub: Monitor uuap	network.	uusub(C)
text file.	newform: Changes the format of a	newform(C)
group.	newgrp: Logs user in to a new	newgrp(C)
news: Print	news items.	news(C)
	news: Print news items.	news(C)
/fetch, store, delete, firstkey,	nextkey: Performs database/	dbm(S)
process.	nice: Changes priority of a	nice(S)
different priority.	nice: Runs a command at a	nice(C)
	nl: Adds line numbers to a file.	nl(C)
list.	nlist: Gets entries from name	nlist(S)
	nm: Prints name list.	nm(CP)
hangups and quits.	nohup: Runs a command immune to	nohup(C)
setjmp, longjmp: Performs a	nonlocal "goto".	setjmp(S)
false: Returns with a	nonzero exit value.	false(C)
	nroff: A text formatter.	nroff(CT)
soelim: Eliminates 'so's from	nroff input.	soelim(CT)
tbl: Formats tables for	nroff or troff.	tbl(CT)
Terminal driving tables for	nroff. term:	term(F)
Formats mathematical text for	nroff, troff. /eqncheck:	eqn(CT)
constructs. deroff: Removes	nroff/troff, tbl, and eqn	deroff(CT)
null: The	null file.	null(M)
	null: The null file.	null(M)
factor: Factor a	number.	factor(C)
random: Generates a random	number.	random(C)
rand, srand: Generates a random	number.	rand(S)
a string to a double-precision	number. strtod, atof: Converts	strtod(S)
atoi, atol: Converts ASCII to	numbers. atof,	atof(S)
library routines and error	numbers. /system services,	Intro(S)
Generates names from inode	numbers. ncheck:	ncheck(C)
nl: Adds line	numbers to a file.	nl(C)
ultoa: Converts	numbers to characters.	ultoa(DOS)
itoa: Converts	numbers to integers.	itoa(DOS)
size: Prints the size of an	object file.	size(CP)
the printable strings in an	object file. strings: Finds	strings(CP)
hdr: Displays selected parts of	object files.	hdr(CP)
Finds ordering relation for an	object library. lorder:	lorder(CP)
8086 Relocatable Format for	Object Modules. 86rel: Intel	86rel(F)
a process until a signal	occurs. pause: Suspends	pause(S)
od: Displays files in	octal format.	od(C)
format.	od: Displays files in octal	od(C)
Invokes a restricted version	of. red:	red(C)
fp_off, fp_seg: Return	offset and segment.	fp_seg(DOS)
new file or rewrites an existing	one. creat: Creates a	creat(S)
and writing. sopen:	Opens a file for shared reading	sopen(DOS)
opensem:	Opens a semaphore.	opensem(S)
fopen, freopen, fdopen:	Opens a stream.	fopen(S)
writing. open:	Opens file for reading or	open(S)
	opensem: Opens a semaphore.	opensem(S)
closedir: Performs directory	operations.	directory(S)

msgctl: Provides message control	operations.	msgctl(S)
msgop: Message	operations.	msgop(S)
semctl: Controls semaphore	operations.	semctl(S)
semop: Performs semaphore	operations.	semop(S)
shmctl: Controls shared memory	operations.	shmctl(S)
shmop: Performs shared memory	operations.	shmop(S)
strdup: Performs string	operations.	string(S)
vector. getopt: Gets	option letter from argument	getopt(S)
stty: Sets the	options for a terminal.	stty(C)
getopt: Parses command	options.	getopt(C)
library. lorder: Finds	ordering relation for an object	lorder(CP)
a directory, or a special or	ordinary file. mknod: Makes	mknod(S)
Copies file archives in and	out. cpio:	cpio(C)
dial: Establishes an	out-going terminal line/	dial(S)
port.	output: Writes a byte to an output	output(DOS)
assembler and link editor	output. a.out: Format	a.out(F)
flushall: Flushes all	output buffers.	flushall(DOS)
ecvt, fcvt, gcvt: Performs	output conversions.	ecvt(S)
cprintf: Formats	output.	cprintf(DOS)
buffered binary input and	output. fread, fwrite: Performs	fread(S)
/vsprintf: Prints formatted	output of a <i>varargs</i> /	vprintf(S)
outp: Writes a byte to an	output port.	outp(DOS)
pr: Prints files on the standard	output.	pr(C)
fprintf, sprintf: Formats	output. printf,	printf(S)
standard buffered input and	output. stdio: Performs	stdio(S)
chown: Changes the	owner and group of a file.	chown(S)
chown: Changes	owner ID.	chown(C)
quot: Summarizes file system	ownership.	quot(C)
and expands files.	pack, pcat, unpack: Compresses	pack(C)
interprocess communication	package. ftok: Standard	stdipc(S)
Gets process, process group, and	parent process IDs. /getppid:	getpid(S)
getopt: Parses command options.	getopt(C)
fdisk: Maintain disk	partitions.	fdisk(C)
hdr: Displays selected	parts of object files.	hdr(CP)
	passwd: Changes login password.	passwd(C)
	passwd: The password file.	passwd(M)
pwadmin: Performs	password aging administration.	pwadmin(C)
setpwent, endpwent: Gets	password file entry. /getpwnam,	getpwent(S)
putpwent: Writes a	password file entry.	putpwent(S)
passwd: The	password file.	passwd(M)
pwcheck: Checks	password file.	pwcheck(C)
getpw: Gets	password for a given user ID.	getpw(S)
getpass: Reads a	password.	getpass(S)
passwd: Changes login	password.	passwd(C)
	paste: Merges lines of files.	paste(CT)
Delivers directory part of	pathname. dirname:	dirname(C)
directory. getcwd: Get the	pathname of current working	getcwd(S)
Removes directory names from	pathnames. basename:	basename(C)
fgrep: Searches a file for a	pattern. grep, egrep,	grep(C)
Searches for and processes a	pattern in a file. awk:	awk(C)
signal occurs.	pause: Suspends a process until	pause(S)
expands files. pack,	pcat, unpack: Compresses and	pack(C)
a process. popen,	pclose: Initiates I/O to or from	popen(S)
bsearch: Performs a binary search.	bsearch(S)
setjmp, longjmp: Performs a nonlocal "goto".	setjmp(S)

qsort: Performs a quicker sort. qsort(S)
 floor, fabs, ceil, fmod: Performs absolute value, floor,/ . . . floor(S)
 bessel, j0, j1, jn, y0, y1, yn: Performs Bessel functions. bessel(S)
 and output. fread, fwrite: Performs buffered binary input . . . fread(S)
 /delete, firstkey, nextkey: Performs database functions. . . . dbm(S)
 closedir: Performs directory operations. directory(S)
 exp, log, pow, sqrt, log10: Performs exponential, logarithm,/ . . . exp(S)
 restores files. sysadmin: Performs file system backups and . . . sysadmin(C)
 sinh, cosh, tanh: Performs hyperbolic functions. sinh(S)
 backup. backup: Performs incremental file system . . . backup(C)
 backup. dump: Performs incremental file system . . . dump(C)
 update. lsearch, lfind: Performs linear search and . . . lsearch(S)
 gamma: Performs log gamma function. gamma(S)
 ecvt, fcvt, gcvt: Performs output conversions. ecvt(S)
 administration. pwadmin: Performs password aging pwadmin(S)
 functions. curses: Performs screen and cursor curses(S)
 semop: Performs semaphore operations. semop(S)
 operations. shmop: Performs shared memory shmop(S)
 and output. stdio: Performs standard buffered input . . . stdio(S)
 strdup: Performs string operations. string(S)
 /tgetflag, tgetstr, tgoto, tputs: Performs terminal functions. termcap(S)
 tan, asin, acos, atan, atan2: Performs trigonometric/ /cos, . . . trig(S)
 chmod: Changes the access permissions of a file or/ chmod(C)
 to a terminal. msg: Permits or denies messages sent . . . msg(C)
 ptx: Generates a permuted index. ptx(CT)
 acct: Format of per-process accounting file. acct(F)
 errno: Sends system error/ error, sys_errlist, sys_nerr, perror(S)
 split: Splits a file into pieces. split(C)
 pipe: pipe: Creates an interprocess pipe(S)
 pipe: Creates an interprocess pipe. pipe(S)
 tee: Creates a tee in a pipe. tee(C)
 data in memory. plock: Lock process, text, or plock(S)
 rewind: Repositions a file pointer in a stream. /ftell, fseek(S)
 lseek: Moves read/write file pointer. lseek(S)
 the current position of the file pointer. tell: Gets tell(DOS)
 or from a process. popen, pclose: Initiates I/O to popen(S)
 outp: Writes a byte to an output port. outp(DOS)
 tty2[A-H]: Interface to serial ports. /tty1[A-H], tty2[a-h], serial(HW)
 exponential,/ exp, log, pow, sqrt, log10: Performs exp(S)
 /Performs exponential, logarithm, power, square root functions. exp(S)
 output. pr: Prints files on the standard pr(C)
 dc: Invokes an arbitrary precision calculator. dc(C)
 statistical processing. prep: Prepares text for prep(CT)
 troff. cw, checkcw, cwcheck: Prepares constant-width text for cw(CT)
 monitor: Prepares execution profile. monitor(S)
 processing. prep: Prepares text for statistical prep(CT)
 cpp: The C language preprocessor. cpp(CP)
 unget: Undoes a previous get of an SCCS file. unget(CP)
 lock: Locks a process in primary memory. lock(S)
 types: Primitive system data types. types(F)
 news: Print news items. news(C)
 printer. imprint: print text files on an IMAGEN imprint(C)
 printer. imprint: print text files on an IMAGEN imprint(CT)
 file. strings: Finds the printable strings in an object strings(CP)
 lp, lp0, lp1, lp2: Line printer device interfaces. lp(HW)

print text files on an IMAGEN	printer. imprint:	imprint(C)
print text files on an IMAGEN	printer. imprint:	imprint(CT)
disable: Turns off terminals and	printers.	disable(C)
Turns on terminals and line	printers. enable:	enable(C)
Formats output.	printf, fprintf, sprintf:	printf(S)
to the lineprinter queue for	printing. lpr: Sends files	lpr(C)
	cal: Prints a calendar.	cal(C)
	prs: Prints an SCCS file.	prs(CP)
	sddate: Prints and sets backup dates.	sddate(C)
	date: Prints and sets the date.	date(C)
activity. sact: Prints current SCCS file editing		sact(CP)
the <i>mm</i> macros. mm: Prints documents formatted with		mm(CT)
output. pr: Prints files on the standard		pr(C)
vprintf, vfprintf, vsprintf: Prints formatted output of a/		vprintf(S)
	banner: Prints large letters.	banner(C)
information. lpstat: prints lineprinter status		lpstat(C)
	nm: Prints name list.	nm(CP)
acctcom: Searches for and	prints process accounting files.	acctcom(C)
	yes: Prints string repeatedly.	yes(C)
stream. head: Prints the first few lines of a		head(C)
XENIX system. uname: Prints the name of the current		uname(C)
backup archive. dumpdir: Prints the names of files on a		dumpdir(C)
	file. size: Prints the size of an object	size(CP)
	names. id: Prints user and group IDs and	id(C)
	pwd: Prints working directory name.	pwd(C)
Runs a command at a different	priority. nice:	nice(C)
nice: Changes	priority of a process.	nice(S)
acct: Enables or disables	process accounting.	acct(S)
acctcom: Searches for and prints	process accounting files.	acctcom(C)
alarm: Sets a	process' alarm clock.	alarm(S)
times: Gets	process and child process times.	times(S)
	init: Process control initialization.	init(M)
exit: Terminates the calling	process.	exit(DOS)
exit, _exit: Terminates a	process.	exit(S)
fork: Creates a new	process.	fork(S)
/getpggrp, getppid: Gets process,	process group, and parent/	getpid(S)
setpggrp: Sets	process group ID.	setpggrp(S)
process group, and parent	process IDs. /Gets process,	getpid(S)
lock: Locks a	process in primary memory.	lock(S)
kill: Terminates a	process.	kill(C)
nice: Changes priority of a	process.	nice(S)
kill: Sends a signal to a	process or a group of processes.	kill(S)
Initiates I/O to or from a	process. popen, pclose:	popen(S)
getpid, getpggrp, getppid: Gets	process, process group, and/	getpid(S)
ptrace: Traces a	process.	ptrace(S)
spawnl, spawnvp: Creates a new	process.	spawn(DOS)
ps: Reports	process status.	ps(C)
memory. plock: Lock	process, text, or data in	plock(S)
times: Gets process and child	process times.	times(S)
wait: Waits for a child	process to stop or terminate.	wait(S)
pause: Suspends a	process until a signal occurs.	pause(S)
sigsem: Signals a	process waiting on a semaphore.	sigsem(S)
checklist: List of file systems	processed by <i>fsck</i>	checklist(F)
awk: Searches for and	processes a pattern in a file.	awk(C)
to a process or a group of	processes. kill: Sends a signal	kill(S)

Awaits completion of background	processes. wait:	wait(C)
intro: Introduces text	processing commands.	Intro(CT)
Prepares text for statistical	processing. prep:	prep(CT)
shutdown: Terminates all	processing.	shutdown(C)
m4: Invokes a macro	processor.	m4(CP)
time profile.	prof: Displays profile data.	prof(CP)
prof: Displays	profil: Creates an execution	profil(S)
monitor: Prepares execution	profile data.	prof(CP)
Creates an execution time	profile.	monitor(S)
at login time.	profile. profil:	profil(S)
assert: Helps verify validity of	profile: Sets up an environment	profil(M)
boot: XENIX boot	program.	assert(S)
etext, edata: Last locations in	program.	boot(HW)
cb: Beautifies C	program. end,	end(S)
lex: Generates	programs.	cb(CP)
and regenerates groups of	programs for lexical analysis.	lex(CP)
stack requirements for C	programs. /Maintains, updates,	make(CP)
xref: Cross-references C	programs. stackuse: Determines	stackuse(CP)
xstr: Extracts strings from C	programs.	xref(CP)
day. asktime:	programs.	xstr(CP)
locking on files. lockf:	Prompts for the correct time of	asktime(C)
operations. msgctl:	Provide semaphores and record	lockf(S)
information.	Provides message control	msgctl(S)
stream. ungetc:	prs: Prints an SCCS file.	prs(CP)
a character or word on a/	ps: Reports process status.	ps(C)
console.	pstat: Reports system	pstat(C)
character or word on a/ putc,	ptrace: Traces a process.	ptrace(S)
environment.	ptx: Generates a permuted index.	ptx(CT)
entry.	Pushes character back into input	ungetc(S)
putc, putchar, fputc, putw:	putc, putchar, fputc, putw: Puts	putc(S)
puts, fputs:	putch: Writes a character to the	putch(DOS)
cputs:	putc, fputc, putw: Puts a	putc(S)
stream.	putenv: Changes or adds value to	putenv(S)
on a/ putc, putchar, fputc,	putpwent: Writes a password file	putpwent(S)
administration.	Puts a character or word on a/	putc(S)
name.	Puts a string on a stream.	puts(S)
Sends files to the lineprinter	Puts a string to the console.	cputs(DOS)
msgget: Gets message	puts, fputs: Puts a string on a	puts(S)
ipcrm: Removes a message	putw: Puts a character or word	putc(S)
qsort: Performs a	pwadmin: Performs password aging	pwadmin(C)
a command immune to hangups and	pwcheck: Checks password file.	pwcheck(C)
ownership.	pwd: Prints working directory	pwd(C)
number.	qsort: Performs a quicker sort.	qsort(S)
number.	queue for printing. lpr:	lpr(C)
ranlib: Converts archives to	queue.	msgget(S)
random: Generates a random	queue, semaphore set or shared/	ipcrm(C)
random libraries.	quicker sort.	qsort(S)
random: Generates a random	quits. nohup: Runs	nohup(C)
random libraries.	quot: Summarizes file system	quot(C)
random: Generates a random	rand, srand: Generates a random	rand(S)
random: Generates a random	random. random: Generates a random	random(C)
random: Generates a random	random libraries.	ranlib(CP)
random: Generates a random	random number.	random(C)
random: Generates a random	random number.	rand(S)
random: Generates a random	random libraries. ranlib: Converts archives to	ranlib(CP)

clockrate: Changes clock rate. clockrate(C)
 FORTRAN into standard FORTRAN. ratfor: Converts Rational ratfor(CP)
 FORTRAN. ratfor: Converts Rational FORTRAN into standard ratfor(CP)
 systems. rcp: Copies files across XENIX rcp(C)
 data to be read. rdchk: Checks to see if there is rdchk(S)
 to see if there is data to be read. rdchk: Checks rdchk(S)
 read: Reads from a file. read(S)
 sopen: Opens a file for shared reading and writing. sopen(DOS)
 or unlocks a file region for reading or writing. /Locks locking(S)
 open: Opens file for reading or writing. open(S)
 getpass: Reads a password. getpass(S)
 defopen, defread: Reads default entries. defopen(S)
 read: Reads from a file. read(S)
 line: Reads one line. line(C)
 mail: Sends, reads or disposes of mail. mail(C)
 lseek: Moves read/write file pointer. lseek(S)
 memory. malloc, free, realloc, calloc: Allocates main malloc(S)
 clock: The system real-time (time of day) clock. clock(M)
 setclock: Sets the system real-time (time of day) clock. setclock(M)
 Specifies what to do upon receipt of a signal. signal: signal(S)
 lockf: Provide semaphores and record locking on files. lockf(S)
 version of. red: Invokes a restricted red(C)
 regular expressions. regex, regcmp: Compiles and executes regex(S)
 expressions. regcmp: Compiles regular regcmp(CP)
 make: Maintains, updates, and regenerates groups of programs. make(CP)
 executes regular expressions. regex, regcmp: Compiles and regex(S)
 compile and match routines. regexp: Regular expression regexp(S)
 locking: Locks or unlocks a file region for reading or writing. locking(S)
 match routines. regexp: Regular expression compile and regexp(S)
 regcmp: Compiles regular expressions. regcmp(CP)
 regcmp: Compiles and executes regular expressions. regex, regex(S)
 sorted files. comm: Selects or rejects lines common to two comm(C)
 intro: Introduction to machine related miscellaneous features/ Intro(HW)
 loader: Finds ordering relation for an object library. loader(CP)
 join: Joins two relations. join(C)
 Modules. 86rel: Intel 8086 Relocatable Format for Object 86rel(F)
 strip: Removes symbols and relocation bits. strip(CP)
 value, floor, ceiling and remainder functions. /absolute floor(S)
 calendar: Invokes a reminder service. calendar(C)
 remote XENIX system. remote: Executes commands on a remote(C)
 remote: Executes commands on a remote XENIX system. remote(C)
 uux: Executes command on remote XENIX. uux(C)
 file. rmdel: Removes a delta from an SCCS rmdel(CP)
 semaphore set or shared/ ipcrm: Removes a message queue, ipcrm(C)
 rmuser: Removes a user from the system. rmuser(C)
 rmdir: Removes directories. rmdir(C)
 unlink: Removes directory entry. unlink(S)
 pathnames. basename: Removes directory names from basename(C)
 rm, rmdir: Removes files or directories. rm(C)
 eqn constructs. derooff: Removes nroff/troff, tbl, and derooff(CT)
 bits. strip: Removes symbols and relocation strip(CP)
 directory. rename: renames a file or rename(DOS)
 rename: renames a file or directory. rename(DOS)
 mv: Moves or renames files and directories. mv(C)
 fsck: Checks and repairs file systems. fsck(C)

uniq: Reports repeated lines in a file. uniq(C)
 yes: Prints string repeatedly. yes(C)
 blocks. df: Report number of free disk df(C)
 clock: Reports CPU time used. clock(S)
 cmchk: Reports hard disk block size. cmchk(C)
 ps: Reports process status. ps(C)
 file. uniq: Reports repeated lines in a uniq(C)
 pstat: Reports system information. pstat(C)
 inter-process/ ipc: Reports the status of ipc(C)
 stream. fseek, ftell, rewind: Repositions a file pointer in a fseek(S)
 Starts/stops the lineprinter request. /lpshut, lpmove: lpshut(C)
 lp, lpr, cancel: Send/cancel requests to lineprinter. lp(C)
 stackuse: Determines stack requirements for C programs. stackuse(CP)
 /Awaits and checks access to a resource governed by a/ waitsem(S)
 system restorer. restore, restor: Invokes incremental file restore(C)
 incremental file system/ restore, restor: Invokes restore(C)
 Invokes incremental file system restorer. restore, restor: restore(C)
 Performs file system backups and restores files. sysadmin: sysadmin(C)
 interpreter). rsh: Invokes a restricted shell (command rsh(C)
 red: Invokes a restricted version of. red(C)
 fp_off, fp_seg: Return offset and segment. fp_seg(DOS)
 stat: Data returned by stat system call. stat(F)
 inp: Returns a byte. inp(DOS)
 console buffer. ungetch: Returns a character to the ungetch(DOS)
 value. abs: Returns an integer absolute abs(S)
 long integer. labs: Returns the absolute value of a labs(DOS)
 strlen: Returns the length of a string. strlen(DOS)
 value. false: Returns with a nonzero exit false(C)
 true: Returns with a zero exit value. true(C)
 col: Filters reverse linefeeds. col(CT)
 in a string. strrev: Reverses the order of characters strrev(DOS)
 pointer in a/ fseek, ftell, rewind: Repositions a file fseek(S)
 creat: Creates a new file or rewrites an existing one. creat(S)
 directories. rm, rmdir: Removes files or rm(C)
 SCCS file. rmdel: Removes a delta from an rmdel(CP)
 rmdir: Deletes a directory. rmdir(DOS)
 rmdir: Removes directories. rmdir(C)
 directories. rm, rmdir: Removes files or rm(C)
 system. rmuser: Removes a user from the rmuser(C)
 chroot: Changes the root directory. chroot(S)
 chroot: Changes root directory for command. chroot(C)
 logarithm, power, square root functions. /exponential, exp(S)
 /system services, library routines and error numbers. Intro(S)
 expression compile and match routines. regexp: Regular regexp(S)
 (command interpreter). rsh: Invokes a restricted shell rsh(C)
 priority. nice: Runs a command at a different nice(C)
 and quits. nohup: Runs a command immune to hangups nohup(C)
 editing activity. sact: Prints current SCCS file sact(CP)
 space allocation. sbrk, brk: Changes data segment sbrk(S)
 and formats input. scanf, fscanf, sscanf: Converts scanf(S)
 bfs: Scans big files. bfs(C)
 help: Asks for help about SCCS commands. help(CP)
 the delta commentary of an SCCS delta. cdc: Changes cdc(CP)
 comb: Combines SCCS deltas. comb(CP)
 Makes a delta (change) to an SCCS file. delta: delta(CP)

sact:	Prints current SCCS file editing activity.	sact(CP)
prs:	Prints an SCCS file.	prs(CP)
rmddl:	Removes a delta from an SCCS file.	rmddl(CP)
	Compares two versions of an SCCS file. sccsdiff:	sccsdiff(CP)
	sccsfile: Format of an SCCS file.	sccsfile(F)
	Undoes a previous get of an SCCS file. unget:	unget(CP)
	val: Validates an SCCS file.	val(CP)
admin:	Creates and administers SCCS files.	admin(CP)
	of an SCCS file. sccsdiff: Compares two versions	sccsdiff(CP)
	file. sccsfile: Format of an SCCS	sccsfile(F)
curses:	Performs screen and cursor functions.	curses(S)
	setcolor: Set screen color.	setcolor(C)
tty[02-n]	- Computer screen. console,	console(HW)
mapstr:	Configure console screen mapping. /mapscrn,	mapkey(M)
	vi: Invokes a screen-oriented display editor.	vedit(C)
	vi: Invokes a screen-oriented display editor.	vi(C)
	vi: Invokes a screen-oriented display editor.	view(C)
install:	Installation shell script.	install(M)
	dates. sddate: Prints and sets backup	sddate(C)
	access to a shared data/ sdenter, sdleave: Synchronizes	sdenter(S)
	shared data segment. sdget, sdfree: Attaches and detaches a	sdget(S)
	detaches a shared data segment. sdget, sdfree: Attaches and	sdget(S)
	shared data access. sdgetv, sdwaitv: Synchronizes	sdgetv(S)
	side-by-side. sdif: Compares files	sdif(C)
	a shared data segment. sdenter, sdleave: Synchronizes access to	sdenter(S)
	data access. sdgetv, sdwaitv: Synchronizes shared	sdgetv(S)
	lsearch, lfind: Performs linear search and update.	lsearch(S)
	bsearch: Performs a binary search.	bsearch(S)
hcreate, hdestroy:	Manages hash search tables. hsearch,	hsearch(S)
tdelete, twalk:	Manages binary search trees. tsearch, tfind,	tsearch(S)
	grep, egrep, fgrep: Searches a file for a pattern.	grep(C)
accounting files. acctcom:	Searches for and prints process	acctcom(C)
pattern in a file. awk:	Searches for and processes a	awk(C)
	sed: Invokes the stream editor.	sed(C)
uniformly distributed. srand48,	seed48, lcong48: Generates	drand48(S)
brkctl:	Allocates data in a far segment.	brkctl(S)
fp_seg:	Return offset and segment. fp_off,	fp_seg(DOS)
	access to a shared data segment. /sdleave: Synchronizes	sdenter(S)
	and detaches a shared data segment. /sdfree: Attaches	sdget(S)
shmget:	Gets a shared memory segment.	shmget(S)
sbrk, brk:	Changes data segment space allocation.	sbrk(S)
	segread: command description.	segread(DOS)
a file. cut:	Cuts out selected fields of each line of	cut(CT)
hdr:	Displays selected parts of object files.	hdr(CP)
to two sorted files. comm:	Selects or rejects lines common	comm(C)
Creates an instance of a binary semaphore. creatsem:	creatsem(S)
opensem:	Opens a semaphore.	opensem(S)
semctl:	Controls semaphore operations.	semctl(S)
semop:	Performs semaphore operations.	semop(S)
ipcrm:	Removes a message queue, semaphore set or shared memory.	ipcrm(C)
	Signals a process waiting on a semaphore. sigsem:	sigsem(S)
	to a resource governed by a semaphore. /and checks access	waitsem(S)
	files. lockf: Provide semaphores and record locking on	lockf(S)
	semget: Gets set of semaphores.	semget(S)
	operations. semctl: Controls semaphore	semctl(S)

	semget: Gets set of semaphores. . . .	semget(S)
operations.	semop: Performs semaphore	semop(S)
lineprinter. lp, lpr, cancel:	Sends/cancel requests to	lp(C)
group of processes. kill:	Sends a signal to a process or a	kill(S)
queue for printing. lpr:	Sends files to the lineprinter	lpr(C)
mail. mail:	Sends, reads or disposes of	mail(C)
/sys_errlist, sys_nerr, errno:	Sends system error messages. . . .	perror(S)
mesg: Permits or denies messages	sent to a terminal.	mesg(C)
tty2[A-H]: Interface to	serial ports. /tty2[a-h],	serial(HW)
calendar: Invokes a reminder	service.	calendar(C)
error/ intro: Introduces system	services, library routines and	Intro(S)
Map of the ASCII character	set. ascii:	ascii(M)
buffering to a stream.	setbuf, setvbuf: Assigns	setbuf(S)
real-time (time of day) clock.	setclock: Sets the system	setclock(M)
	setcolor: Set screen color.	setcolor(C)
setuid,	setgid: Sets user and group IDs. . . .	setuid(S)
getgrent, getgrgid, getgrnam,	setgrent, endgrent: Get group/	getgrent(S)
nonlocal "goto".	setjmp, longjmp: Performs a	setjmp(S)
keys.	setkey: Assigns the function	setkey(M)
table.	setmnt: Establishes /etc/mnttab	setmnt(C)
	setmode: Sets translation mode. . . .	setmode(DOS)
	setpgrp: Sets process group ID. . . .	setpgrp(S)
getpwent, getpwuid, getpwnam,	setpwent, endpwent: Gets/	getpwent(S)
alarm:	Sets a process' alarm clock.	alarm(S)
to one character. strset:	Sets all characters in a string	strset(DOS)
mask. umask:	Sets and gets file creation	umask(S)
sddate: Prints and	sets backup dates.	sddate(C)
execution. env:	Sets environment for command	env(C)
modification times. utime:	Sets file access and	utime(S)
umask:	Sets file-creation mode mask. . . .	umask(C)
setpgrp:	Sets process group ID.	setpgrp(S)
tset:	Sets terminal modes.	tset(C)
speed, and line/ getty:	Sets terminal type, modes,	getty(M)
base. Cmos: Displays and	sets the configuration data	cmos(HW)
date: Prints and	sets the date.	date(C)
stty:	Sets the options for a terminal. . . .	stty(C)
of day) clock. setclock:	Sets the system real-time (time	setclock(M)
stime:	Sets the time.	stime(S)
setmode:	Sets translation mode.	setmode(DOS)
time. profile:	Sets up an environment at login	profile(M)
setuid, setgid:	Sets user and group IDs.	setuid(S)
ulimit: Gets and	sets user limits.	ulimit(S)
modification dates of files.	settime: Changes the access and	settime(C)
gettydefs: Speed and terminal	settings used by getty.	gettydefs(F)
group IDs.	setuid, setgid: Sets user and	setuid(S)
stream. setbuf,	setvbuf: Assigns buffering to a	setbuf(S)
data in a/ sputl,	sgetl: Accesses long integer	sputl(S)
interpreter. sh:	Invokes the shell command	sh(C)
sdgetv, sdwaitv: Synchronizes	shared data access.	sdgetv(S)
Synchronizes access to a	shared data segment. /sdleave:	sdenter(S)
sdfree: Attaches and detaches a	shared data segment. sdget,	sdget(S)
message queue, semaphore set or	shared memory. ipcrm: Removes a	ipcrm(C)
shmctl: Controls	shared memory operations.	shmctl(S)
shmop: Performs	shared memory operations.	shmop(S)
shmget: Gets a	shared memory segment.	shmget(S)

sopen: Opens a file for	shared reading and writing.	sopen(DOS)
rsh: Invokes a restricted	shell (command interpreter).	rsh(C)
sh: Invokes the	shell command interpreter.	sh(C)
shV: Invokes the	shell command interpreter.	shV(C)
C-like syntax. csh: Invokes a	shell command interpreter with	csh(C)
system: Executes a	shell command.	system(S)
install: Installation	shell script.	install(M)
TZ: Time zone	shell variable.	tz(M)
operations.	shmctl: Controls shared memory	shmctl(S)
segment.	shmget: Gets a shared memory	shmget(S)
operations.	shmop: Performs shared memory	shmop(S)
nap: Suspends execution for a	short interval.	nap(S)
halts the CPU.	shutdown: Flushes block I/O and	shutdown(S)
processing.	shutdown: Terminates all	shutdown(C)
interpreter.	shV: Invokes the shell command	shV(C)
sdiff: Compares files	side-by-side.	sdiff(C)
Suspends a process until a	signal occurs. pause:	pause(S)
what to do upon receipt of a	signal. signal: Specifies	signal(S)
upon receipt of a signal.	signal: Specifies what to do	signal(S)
of processes. kill: Sends a	signal to a process or a group	kill(S)
semaphore. sigsem:	Signals a process waiting on a	sigsem(S)
gsignal: Implements software	signals. ssignal,	ssignal(S)
waiting on a semaphore.	sigsem: Signals a process	sigsem(S)
atan2: Performs trigonometric/	sin, cos, tan, asin, acos, atan,	trig(S)
hyperbolic functions.	sinh, cosh, tanh: Performs	sinh(S)
cmchk: Reports hard disk block	size.	cmchk(C)
chsize: Changes the	size of a file.	chsize(S)
size: Prints the	size of an object file.	size(CP)
object file.	size: Prints the size of an	size(CP)
interval.	sleep: Suspends execution for an	sleep(C)
interval.	sleep: Suspends execution for an	sleep(S)
current/ ttyslot: Finds the	slot in the utmp file of the	ttyslot(S)
spline: Interpolates	smooth curve.	spline(CP)
nroff input.	soelim: Eliminates 'so's from	soelim(CT)
ssignal, gsignal: Implements	software signals.	ssignal(S)
reading and writing.	sopen: Opens a file for shared	sopen(DOS)
qsort: Performs a quicker	sort.	qsort(S)
	sort: Sorts and merges files.	sort(C)
or rejects lines common to two	sorted files. comm: Selects	comm(C)
look: Finds lines in a	sorted list.	look(CT)
tsort: Sorts a file topologically.		tsort(CP)
sort: Sorts and merges files.		sort(C)
soelim: Eliminates	'so's from nroff input.	soelim(CT)
an error message file from C	source. mkstr: Creates	mkstr(CP)
sbrk, brk: Changes data segment	space allocation.	sbrk(S)
process.	spawnl, spawnvp: Creates a new	spawn(DOS)
spawnl,	spawnvp: Creates a new process.	spawn(DOS)
movedata: Copies bytes from a	specific address.	movedata(DOS)
cron: Executes commands at	specified times.	cron(C)
receipt of a signal. signal:	Specifies what to do upon	signal(S)
/Sets terminal type, modes,	speed, and line discipline.	getty(M)
by getty. gettydefs:	Speed and terminal settings used	gettydefs(F)
hashcheck: Finds spelling/	spell, hashmake, spellin,	spell(CT)
spelling/ spell, hashmake,	spellin, hashcheck: Finds	spell(CT)
spellin, hashcheck: Finds	spelling errors. /hashmake,	spell(CT)

curve. spline: Interpolates smooth spline(CP)
 pieces. split: Splits a file into split(C)
 split: Splits a file into pieces. split(C)
 context. csplit: Splits files according to csplit(C)
 into a/ frexp, ldexp, modf: Splits floating-point number frexp(S)
 uuclean: Clean-up the uucp spool directory. uuclean(C)
 Configures the lineprinter spooling system. lpadmin: lpadmin(C)
 printf, fprintf, sprintf: Formats output. printf(S)
 integer data in a/ sputl, sgetl: Accesses long sputl(S)
 exponential, / exp, log, pow, sqrt, log10: Performs exp(S)
 exponential, logarithm, power, square root functions. /Performs exp(S)
 number. rand, srand: Generates a random rand(S)
 Generates uniformly/ srand48, seed48, lcong48: drand48(S)
 input. scanf, fscanf, sscanf: Converts and formats scanf(S)
 software signals. ssignal, gsignal: Implements ssignal(S)
 programs. stackuse: Determines stack requirements for C stackuse(CP)
 requirements for C programs. stackuse: Determines stack stackuse(CP)
 output. stdio: Performs standard buffered input and stdio(S)
 Converts Rational FORTRAN into standard FORTRAN. ratfor: ratfor(CP)
 gets: Gets a string from the standard input. gets(CP)
 communication package. ftok: Standard interprocess stdipc(S)
 pr: Prints files on the standard output. pr(C)
 lpsched, lpshut, lpmove: Starts/stops the lineprinter/ lpsched(C)
 system call. stat: Data returned by stat stat(F)
 stat, fstat: Gets file status. stat(S)
 stat: Data returned by stat system call. stat(F)
 prep: Prepares text for statistical processing. prep(CT)
 ustat: Gets file system statistics. ustat(S)
 fileno: Determines stream status. ferror, feof, clearerr, ferror(S)
 lpsched, lpshut, lpmove: status information. lpstat(C)
 ustat: prints lineprinter status inquiry and job control. uustat(C)
 communication/ ipc: Reports the status of inter-process ipc(C)
 ps: Reports process status. ps(C)
 stat, fstat: Gets file status. stat(S)
 buffered input and output. stdio: Performs standard stdio(S)
 stime: Sets the time. stime(S)
 Waits for a child process to stop or terminate. wait: wait(S)
 nextkey:/ dbminit, fetch, store, delete, firstkey, dbm(S)
 operations. strdup: Performs string string(S)
 sed: Invokes the stream editor. sed(C)
 fflush: Closes or flushes a stream. fclose, fclose(S)
 Gets a character from a stream. fgetc, fgetchar: fgetc(DOS)
 fopen, freopen, fdopen: Opens a stream. fopen(S)
 fputc: Write a character to a stream. fputc, fputc(DOS)
 Repositions a file pointer in a stream. fseek, ftell, rewind: fseek(S)
 Gets character or word from a stream. /getchar, fgetc, getw: getc(S)
 fgets: Gets a string from a stream. gets, gets(S)
 Prints the first few lines of a stream. head: head(C)
 Puts a character or word on a stream. /putchar, fputc, putw: putc(S)
 puts, fputs: Puts a string on a stream. puts(S)
 setvbuf: Assigns buffering to a stream. setbuf, setbuf(S)
 clearerr, fileno: Determines stream status. ferror, feof, ferror(S)
 Pushes character back into input stream. ungetc: ungetc(S)
 fclose, fcloseall: Closes streams. fclose(DOS)
 gets, fgets: Gets a string from a stream. gets(S)

gets: Gets a	string from the standard input. . . .	gets(CP)
puts, fputs: Puts a	string on a stream.	puts(S)
strdup: Performs	string operations.	string(S)
yes: Prints	string repeatedly.	yes(C)
strlen: Returns the length of a	string.	strlen(DOS)
the order of characters in a	string. strrev: Reverses	strrev(DOS)
strtod, atof: Converts a	string to a double-precision/	strtod(S)
strtol, atol, atoi: Converts	string to integer.	strtol(S)
strset: Sets all characters in a	string to one character.	strset(DOS)
cputs: Puts a	string to the console.	cputs(DOS)
strings in an object file.	strings: Finds the printable	strings(CP)
xstr: Extracts	strings from C programs.	xstr(CP)
strings: Finds the printable	strings in an object file.	strings(CP)
relocation bits.	strip: Removes symbols and	strip(CP)
string.	strlen: Returns the length of a . . .	strlen(DOS)
characters to lowercase.	strlwr: Converts uppercase	strlwr(DOS)
characters in a string.	strrev: Reverses the order of	strrev(DOS)
string to one character.	strset: Sets all characters in a	strset(DOS)
to a double-precision number.	strtod, atof: Converts a string . . .	strtod(S)
string to integer.	strtol, atol, atoi: Converts	strtol(S)
mount: Mounts a file	structure.	mount(C)
umount: Dismounts a file	structure.	umount(C)
characters to uppercase.	strupr: Converts lowercase	strupr(DOS)
terminal.	stty: Sets the options for a	stty(C)
of a document.	style: Analyzes characteristics . . .	style(CT)
or another user.	su: Makes the user a super-user . . .	su(C)
counts blocks in a file.	sum: Calculates checksum and	sum(C)
du: Summarizes disk usage.		du(C)
ownership. quot: Summarizes file system		quot(C)
sync: Updates the	super-block.	sync(C)
sync: Updates the	super-block.	sync(S)
su: Makes the user a	super-user or another user.	su(C)
terminals: List of	supported terminals.	terminals(M)
signal occurs. pause: Suspends a process until a		pause(S)
interval. nap: Suspends execution for a short		nap(S)
interval. sleep: Suspends execution for an		sleep(C)
interval. sleep: Suspends execution for an		sleep(S)
swab: Swaps bytes.		swab(S)
swab: Swaps bytes.		swab(S)
strip: Removes	symbols and relocation bits.	strip(CP)
	sync: Updates the super-block. . . .	sync(C)
	sync: Updates the super-block. . . .	sync(S)
data segment. sdenter, sdleave: Synchronizes access to a shared		sdenter(S)
sdgetv, sdwaitv: Synchronizes shared data access. . . .		sdgetv(S)
command interpreter with C-like	syntax. csh: Invokes a shell	csh(C)
Checks C language usage and	syntax. lint:	lint(CP)
backups and restores files.	sysadmin: Performs file system . . .	sysadmin(C)
Sends system error/ perror,	sys_errlist, sys_nerr, errno:	perror(S)
error/ perror, sys_errlist,	sys_nerr, errno: Sends system	perror(S)
Automatically boots the	system. autoboot:	autoboot(M)
config: Configures a XENIX	system.	config(CP)
cu: Calls another XENIX	system.	cu(C)
the lineprinter spooling	system. lpadmin: Configures	lpadmin(C)
lpinit: Adds new lineprinters to	system.	lpinit(C)
mkfs: Constructs a file	system.	mkfs(C)

mkuser: Adds a login ID to the	system.	mkuser(C)
mount: Mounts a file	system.	mount(S)
commands on a remote XENIX	system. remote: Executes	remote(C)
rmuser: Removes a user from the	system.	rmuser(C)
umount: Unmounts a file	system.	umount(S)
the name of the current XENIX	system. uname: Prints	uname(C)
Gets name of current XENIX	system. uname:	uname(S)
who: Lists who is on the	system.	who(C)
identification file.	systemid: The Micnet system	systemid(M)
haltsys: Closes out the file	systems and halts the CPU.	haltsys(C)
fsck: Checks and repairs file	systems.	fsck(C)
checklist: List of file	systems processed by <i>fsck</i>	checklist(F)
rcp: Copies files across XENIX	systems.	rcp(C)
alias hash: Micnet alias hash	table generator.	alias hash(M)
Master device information	table. master:	master(F)
Format of mounted file system	table. mnttab:	mnttab(F)
setmnt: Establishes /etc/mnttab	table.	setmnt(C)
tbl: Formats	tables for nroff or troff.	tbl(CT)
term: Terminal driving	tables for nroff.	term(F)
hdestroy: Manages hash search	tables. hsearch, hcreate,	hsearch(S)
ctags: Creates a	tags file.	ctags(CP)
a file.	tail: Delivers the last part of	tail(C)
Performs/ sin, cos,	tan, asin, acos, atan, atan2:	trig(S)
functions. sinh, cosh,	tanh: Performs hyperbolic	sinh(S)
backup: Incremental dump	tape format.	backup(F)
dump: Incremental dump	tape format.	dump(F)
	tar: archive format.	tar(F)
	tar: Archives files.	tar(C)
deroff: Removes nroff/troff,	tbl, and eqn constructs.	deroff(CT)
troff.	tbl: Formats tables for nroff or	tbl(CT)
search trees. tsearch, tfind,	tdelete, twalk: Manages binary	tsearch(S)
	tee: Creates a tee in a pipe.	tee(C)
tee: Creates a	tee in a pipe.	tee(C)
temporary file. tmpnam,	tempnam: Creates a name for a	tmpnam(S)
tmpfile: Creates a	temporary file.	tmpfile(S)
tempnam: Creates a name for a	temporary file. tmpnam,	tmpnam(S)
	term: Conventional names.	term(CT)
	for nroff. term: Terminal driving tables	term(F)
	data base. termcap: Terminal capability	termcap(M)
	termcap: Terminal capability data base.	termcap(M)
Generates a filename for a	terminal. ctermid:	ctermid(S)
nroff. term: Terminal driving tables for	terminal functions. /tgetflag,	term(F)
tgetstr, tgoto, tputs: Performs	terminal interface.	termcap(S)
termio: General	terminal interface.	termio(M)
tty: Special	terminal interface.	tty(M)
dial: Establishes an out-going	terminal line connection.	dial(S)
or denies messages sent to a	terminal. mesg: Permits	mesg(C)
tset: Sets	terminal modes.	tset(C)
gettydefs: Speed and	terminal settings used by getty.	gettydefs(F)
stty: Sets the options for a	terminal.	stty(C)
isatty: Finds the name of a	terminal. ttyname,	ttyname(S)
line discipline. getty: Sets	terminal type, modes, speed, and	getty(M)
enable: Turns on	terminals and line printers.	enable(C)
disable: Turns off	terminals and printers.	disable(C)
tty: Login	terminals file.	ttys(M)

terminals.	terminals: List of supported	terminals(M)
tty: Gets the	terminal's name.	tty(C)
terminals: List of supported	terminals.	terminals(M)
for a child process to stop or	terminate. wait: Waits	wait(S)
exit, _exit: Terminates a process.		exit(S)
kill: Terminates a process.		kill(C)
shutdown: Terminates all processing.		shutdown(C)
exit: Terminates the calling process.		exit(DOS)
interface.	termio: General terminal	termio(M)
	test: Tests conditions.	test(C)
test: Tests conditions.		test(C)
ed: Invokes the	text editor.	ed(C)
ex: Invokes a	text editor.	ex(C)
newform: Changes the format of a	text file.	newform(C)
diff: Compares two	text files.	diff(C)
imprint: print	text files on an IMAGEN printer.	imprint(C)
imprint: print	text files on an IMAGEN printer.	imprint(CT)
eqncheck: Formats mathematical	text for nroff, troff. /checkeq.	eqn(CT)
prep: Prepares	text for statistical processing.	prep(CT)
cwcheck: Prepares constant-width	text for troff. cw, checkcw,	cw(CT)
nroff: A	text formatter.	nroff(CT)
plock: Lock process,	text, or data in memory.	plock(S)
intro: Introduces	text processing commands.	Intro(CT)
troff: Typesets	text.	troff(CT)
binary search trees. tsearch,	tfind, tdelete, twalk: Manages	tsearch(S)
tgetstr, tgoto, tputs: Performs/	tgetent, tgetnum, tgetflag,	termcap(S)
Performs/ tgetent, tgetnum,	tgetflag, tgetstr, tgoto, tputs:	termcap(S)
tgoto, tputs: Performs/ tgetent,	tgetnum, tgetflag, tgetstr,	termcap(S)
tgetent, tgetnum, tgetflag,	tgetstr, tgoto, tputs: Performs/	termcap(S)
/tgetnum, tgetflag, tgetstr,	tgoto, tputs: Performs terminal/	termcap(S)
Executes commands at a later	time. at, batch:	at(C)
	time, ftime: Gets time and date.	time(S)
clock: The system real-time	(time of day) clock.	clock(M)
Sets the system real-time	(time of day) clock. setclock:	setclock(M)
Sets up an environment at login	time. profile:	profile(M)
stime: Sets the	time.	stime(S)
Executes commands at specified	times. cron:	cron(C)
Gets process and child process	times. times:	times(S)
file access and modification	times. utime: Sets	utime(S)
file.	tmpfile: Creates a temporary	tmpfile(S)
for a temporary file.	tmpnam, tempnam: Creates a name	tmpnam(S)
conv, toupper, tolower,	toascii: Translates characters.	conv(S)
characters. conv, toupper,	tolower, toascii: Translates	conv(S)
topology files.	top, top.next: The Micnet	top(M)
files. top,	top.next: The Micnet topology	top(M)
tsort: Sorts a file	topologically.	tsort(CP)
top, top.next: The Micnet	topology files.	top(M)
modification times of a file.	touch: Updates access and	touch(C)
Translates characters. conv,	toupper, tolower, toascii:	conv(S)
/tgetflag, tgetstr, tgoto,	tputs: Performs terminal/	termcap(S)
tr: Translates characters.		tr(C)
ptrace: Traces a process.		ptrace(S)
conv, toupper, tolower, toascii:	Translates characters.	conv(S)
tr: Translates characters.		tr(C)
setmode: Sets	translation mode.	setmode(DOS)

ftw: Walks a file tree. ftw(S)
twalk: Manages binary search trees. tsearch, tfind, tdelete, tsearch(S)
acos, atan, atan2: Performs trigonometric functions. /asin, trig(S)
Prepares constant-width text for troff. cw, checkcw, cwcheck: cw(CT)
mathematical text for nroff, troff. /eqncheck: Formats eqn(CT)
tbl: Formats tables for nroff or troff. tbl(CT)
troff: Typesets text. troff(CT)
Manages binary search trees. tsearch, tfind, tdelete, twalk: tsearch(S)
tset: Sets terminal modes. tset(C)
topologically. tsort: Sorts a file tsort(CP)
tty: Gets the terminal's name. tty(C)
tty: Special terminal interface. tty(M)
screen. console, tty[02-n] - Computer console(HW)
tty2[A-H]: Interface to serial/ tty1[a-h], tty1[A-H], tty2[a-h], serial(HW)
Interface to serial/ tty1[a-h], tty1[A-H], tty2[a-h], tty2[A-H]: serial(HW)
tty1[a-h], tty1[A-H], tty2[a-h], tty2[A-H]: Interface to serial/ serial(HW)
to serial/ tty1[a-h], tty1[A-H], tty2[a-h], tty2[A-H]: Interface serial(HW)
of a terminal. ttyname, isatty: Finds the name ttyname(S)
ttys: Login terminals file. ttys(M)
utmp file of the current user. ttyslot: Finds the slot in the ttyslot(S)
printers. disable: Turns off terminals and disable(C)
accton: Turns on accounting. accton(C)
printers. enable: Turns on terminals and line enable(C)
trees. tsearch, tfind, tdelete, twalk: Manages binary search tsearch(S)
dtype: Determines disk type. dtype(C)
file: Determines file type. file(C)
getty: Sets terminal type, modes, speed, and line/ getty(M)
types. types: Primitive system data types(F)
types: Primitive system data types. types(F)
mmt: Typesets documents. mmt(CT)
troff: Typesets text. troff(CT)
TZ: Time zone shell variable. tz(M)
/localtime, gmtime, asctime, tzset: Converts date and time to/ ctime(S)
limits. ulimit: Gets and sets user ulimit(S)
characters. ultoa: Converts numbers to ultoa(DOS)
creation mask. umask: Sets and gets file umask(S)
mask. umask: Sets file-creation mode umask(C)
structure. umount: Dismounts a file umount(C)
umount: Unmounts a file system. . . . umount(S)
XENIX system. uname: Gets name of current uname(S)
current XENIX system. uname: Prints the name of the uname(C)
file. unset: Undoes a previous get of an SCCS unset(CP)
an SCCS file. unset: Undoes a previous get of unset(CP)
into input stream. unsetc: Pushes character back unsetc(S)
the console buffer. unsetch: Returns a character to unsetch(DOS)
seed48, lcong48: Generates uniformly distributed. srand48, drand48(S)
a file. uniq: Reports repeated lines in uniq(C)
mktemp: Makes a unique filename. mktemp(S)
units: Converts units. units(C)
units. units: Converts units. units(C)
unlink: Removes directory entry. unlink(S)
reading or/ locking: Locks or unlocks a file region for locking(S)
umount: Unmounts a file system. umount(S)
files. pack, pcat, unpack: Compresses and expands pack(C)
Performs linear search and update. lsearch, lfind: lsearch(S)

times of a file.	touch:	Updates access and modification	touch(C)
of programs.	make:	Maintains, updates, and regenerates groups	make(CP)
	sync:	Updates the super-block.	sync(C)
	sync:	Updates the super-block.	sync(S)
lowercase.	strlwr:	Converts uppercase characters to	strlwr(DOS)
Converts lowercase characters to	uppercase.	strupr:	strupr(DOS)
lint:	Check C language	usage and syntax.	lint(CP)
diction:	Checks language	usage.	diction(CT)
du:	Summarizes disk	usage.	du(C)
explain:	Corrects language	usage.	explain(CT)
checkmm, mmcheck:	Checks	usage of MM macros.	checkmm(CT)
clock:	Reports CPU time	used.	clock(S)
user. su:	Makes the	user a super-user or another	su(C)
	id:	Prints user and group IDs and names.	id(C)
setuid, setgid:	Sets	user and group IDs.	setuid(S)
Gets the login name of the	user.	cuserid:	cuserid(S)
/getgid, getegid:	Gets real	user, effective user, real/	getuid(S)
	environ:	The user environment.	environ(M)
rmuser:	Removes a	user from the system.	rmuser(C)
getpw:	Gets password for a given	user ID.	getpw(S)
	newgrp:	Logs user in to a new group.	newgrp(C)
	ulimit:	Limits: Gets and sets	ulimit(S)
logname:	Finds login name of	user.	logname(S)
group/ /	Gets real user, effective	user, real group, and effective	getuid(S)
the user a super-user or another	user. su:	Makes	su(C)
in the utmp file of the current	user.	ttyslot:	ttyslot(S)
write:	Writes to another	user.	write(C)
finger:	Finds information about	users.	finger(C)
	wall:	Writes to all	wall(C)
	statistics.	ustat:	ustat(S)
	modification times.	utime:	utime(S)
	utmp, wtmp:	Formats of utmp and wtmp entries.	utmp(M)
endutent, utmpname:	Accesses	utmp file entry.	getut(S)
ttyslot:	Finds the slot in the	utmp file of the current user.	ttyslot(S)
	wtmp entries.	utmp, wtmp:	utmp(M)
	entry. endutent,	utmpname:	getut(S)
	directory.	uuclean:	uuclean(C)
uuinstall:	Administer	UUCP control files.	uuinstall(C)
uusub:	Monitor	uucp network.	uusub(C)
uuclean:	Clean-up the	uucp spool directory.	uuclean(C)
	control. uustat:	uucp status inquiry and job	uustat(C)
	control files.	uuinstall:	uuinstall(C)
	file copy. uuto,	uupick:	uuto(C)
	job control.	uustat:	uustat(C)
		uusub:	uusub(C)
XENIX-to-XENIX file copy.	uuto, uupick:	Public	uuto(C)
XENIX.	uux:	Executes command on remote	uux(C)
	val:	Validates an SCCS file.	val(CP)
	val:	Validates an SCCS file.	val(CP)
	assert:	Helps verify	assert(S)
abs:	Returns an integer absolute	value.	abs(S)
	Returns with a nonzero exit	value. false:	false(C)
ceil, fmod:	Performs absolute	value, floor, ceiling and/ /fabs,	floor(S)
	getenv:	Gets value for environment name.	getenv(S)
labs:	Returns the absolute	value of a long integer.	labs(DOS)

putenv: Changes or adds value to environment. putenv(S)
 true: Returns with a zero exit value. true(C)
 varargs: Variable argument list. varargs(F)
 varargs: Variable argument list. varargs(F)
 TZ: Time zone shell variable. tz(M)
 Gets option letter from argument vector. getopt: getopt(S)
 assert: Helps verify validity of program. assert(S)
 red: Invokes a restricted version of. red(C)
 scsdiff: Compares two versions of an SCCS file. scsdiff(CP)
 formatted output of a/ vprintf, vfprintf, vsprintf: Prints vprintf(S)
 display editor. vi: Invokes a screen-oriented vedit(C)
 display editor. vi: Invokes a screen-oriented vi(C)
 display editor. vi: Invokes a screen-oriented view(C)
 file system: Format of a system volume. filesystem(F)
 Prints formatted output of a/ vprintf, vfprintf, vsprintf: vprintf(S)
 output of a/ vprintf, vfprintf, vsprintf: Prints formatted vprintf(S)
 background processes. wait: Awaits completion of wait(C)
 to stop or terminate. wait: Waits for a child process wait(S)
 sigsem: Signals a process waiting on a semaphore. sigsem(S)
 stop or terminate. wait: Waits for a child process to wait(S)
 checks access to a resource/ waitsem, nbwaitsem: Awaits and waitsem(S)
 ftw: Walks a file tree. ftw(S)
 wall: Writes to all users. wall(C)
 characters. wc: Counts lines, words and wc(C)
 whodo: Determines who is doing what. whodo(C)
 what. whodo: Determines who is doing whodo(C)
 hyphen: Finds hyphenated words. hyphen(CT)
 cd: Changes working directory. cd(C)
 chdir: Changes the working directory. chdir(S)
 Get the pathname of current working directory. getcwd: getcwd(S)
 pwd: Prints working directory name. pwd(C)
 fputc, fputchar: Write a character to a stream. fputc(DOS)
 write: Writes to a file. write(S)
 write: Writes to another user. write(C)
 outp: Writes a byte to an output port. outp(DOS)
 console. putch: Writes a character to the putch(DOS)
 putpwent: Writes a password file entry. putpwent(S)
 write: Writes to a file. write(S)
 wall: Writes to all users. wall(C)
 write: Writes to another user. write(C)
 a file region for reading or writing. /Locks or unlocks locking(S)
 open: Opens file for reading or writing. open(S)
 a file for shared reading and writing. sopen: Opens sopen(DOS)
 utmp, wtmp: Formats of utmp and wtmp entries. utmp(M)
 entries. utmp, wtmp: Formats of utmp and wtmp utmp(M)
 commands. xargs: Constructs and executes xargs(C)
 asx: XENIX 8086/186/286 Assembler. asx(CP)
 masm: Invokes the XENIX assembler. masm(CP)
 boot: XENIX boot program. boot(HW)
 intro: Introduces XENIX commands. Intro(C)
 commands. intro: Introduces XENIX Development System Intro(CP)
 netutil: Administers the XENIX network. netutil(C)
 config: Configures a XENIX system. config(CP)
 cu: Calls another XENIX system. cu(C)
 Executes commands on a remote XENIX system. remote: remote(C)

```

Prints the name of the current XENIX system.  uname: . . . . . uname(C)
uname: Gets name of current XENIX system. . . . . uname(S)
    rcp: Copies files across XENIX systems. . . . . rcp(C)
        dosld: XENIX to MS-DOS cross linker. . . dosld(CP)
uux: Executes command on remote XENIX. . . . . uux(C)
    uuto, uupick: Public XENIX-to-XENIX file copy. . . uuto(C)
        entries from files. xlist, fxlist: Gets name list . . . . xlist(S)
            programs. xref: Cross-references C . . . . . xref(CP)
            programs. xstr: Extracts strings from C . . . . . xstr(CP)
functions.  bessel, j0, j1, jn, y0, y1, yn: Performs Bessel . . . . . bessel(S)
    bessel, j0, j1, jn, y0, y1, yn: Performs Bessel/ . . . . . bessel(S)
    compiler-compiler. yacc: Invokes a . . . . . yacc(CP)
        yes: Prints string repeatedly. . . . . yes(C)
    bessel, j0, j1, jn, y0, y1, yn: Performs Bessel functions. . . . . bessel(S)
    true: Returns with a zero exit value. . . . . true(C)
        TZ: Time zone shell variable. . . . . tz(M)

```
